Workers involved:															
Beginning in period (in thousands)	376.0	323.9	15.7	50.1	15.3	69.5	76.6	26.2	8.2	7.6	24.0	12.3	7.2	29.7	199.1
In effect during period (in thousands)	391.0	584.1	28.5	56.9	96.8	93.9	119.3	47.0	38.0	12.0	28.4	39.7	18.7	42.3	207.0
Days idle:															
Number (in thousands)	8,499.0	7,079.0	454.3	500.2	869.7	931.4	1,433.0	651.2	665.4	170.0	39.7	380.6	321.5	314.6	3,707.4
Percent of estimated working time[1]	.04	.03	.02	.02	.04	.04	.06	.04	.03	.01	.02	.02	.02	.02	.07

[1] Agricultural and government employees are included in the total employed and total working time: private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in "'Total economy' measure of strike idleness," *Monthly Labor Review*, October 1968, pp. 54-56.

[1] Area is generally the Standard Metropolitan Statistical Area (SMSA), exclusive of farms. L.A.-Long Beach, Anaheim, Calif. is a combination of two SMSA's, and N.Y., N.Y.-Northeastern N.J. and Chicago, Ill.-Northwestern Ind. are the more extensive Standard Consolidated Areas. Area definitions are those established by the Office of Management and Budget in 1973, except for Denver-Boulder, Colo. which does not include Douglas County. Definitions do not include revisions made since 1973.

[2] Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:.

M - Every month.

1 - January, March, May, July, September, and November.

2 - February, April, June, August, October, and December.

[3] Regions are defined as the four Census regions.

The population size classes are aggregations of areas which have urban population as defined:

A-1 - More than 4,000,000.

A-2 - 1,250,000 to 4,000,000.

B - 385,000 to 1,250,000

C - 75,000 to 385,000.

D - Less than 75,000.

Population size class A is the aggregation of population size classes A-1 and A-2.

- Data not available.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Because each local index is a small subset of the national index, it has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error than the national index. As a result, local area indexes show greater volatility than the national index, although their long-term trends are quite similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in escalator clauses.

32. Annual data: Consumer Price Index all items and major groups

Series	1977	1978	1979	1980	1981	1982	1983	1984	1985

Sweden	3.1	2.8	3.1	3.0	3.0	2.9	2.8	2.7	2.8

[1] Quarterly rates are for the first month of the quarter.

[2] Major changes in the Italian labor force survey, introduced in 1977, resulted in a large increase in persons enumerated as unemployed. However, many persons reported that they had not actively sought work in the past 30 days, and they have been provisionally excluded for comparability with U.S. concepts. Inclusion of such persons would more than double the Italian unemployment rate shown.

NOTE: Quarterly and monthly figures for France, Germany, and Great Britain are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures.

46. Annual data: Employment status of the civilian working-age population, ten countries

(Numbers in thousands)

Lost workdays	38.4	35.4	36.2	36.1	35.8	35.9	35.8	37.0	41.1

[1] Total cases include fatalities.

[2] The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as: (N/EH) X 200,000, where:

N = number of injuries and illnesses or lost workdays.

EH = total hours worked by all employees during calendar year.

200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year.)

[3] Excludes farms with fewer than 11 employees since 1976.

Transportation and Material Moving Occupations. Bulletin 2250-21, 16 pp., $1.25 (GPO Stock No. 029-001-02886-5).

Complete set of 21 reprints, $22 (GPO Stock No. 029-001-02865-2).

Technology and Its Impact on Labor in Four Industries. Bulletin 2242, 46 pp., $2.75 (GPO Stock No. 029-001-02899-7). Appraises some of the technological changes emerging among selected American industries (tires and inner tubes, aluminum, aerospace, and commercial banking) and discusses the impact of these changes on productivity and labor over the next 5 to 10 years.

Area Wage Surveys

These bulletins cover office, professional, technical, maintenance, custodial, and material movement jobs in major metropolitan areas. The annual series is available by subscription for $103 per year. Individual area bulletins are also available separately.

Beginning in January 1987, the current program of annual surveys of 70 areas will change to a program of 90 surveys—35 areas surveyed every year and two groups of 29 areas surveyed in alternate years.

Chicago, Illinois, Metropolitan Area, March 1986. Bulletin 3035-9, 58 pp., $3 (GPO Stock No. 829-001-00081-1).

Industry Wage Surveys

These studies include results from the latest BLS survey of wages and supplemental benefits, with detailed occupational data for the Nation, regions, and selected areas (where available). Data are useful for wage and salary administration, union contract negotiation, arbitration, and Government policy considerations.

Textile Dyeing and Finishing, June 1985. Bulletin 2260, 56 pp., $3.25 (GPO Stock No. 029-001-02901-2).

Periodicals

CPI Detailed Report. Each issue provides a comprehensive report on price movements for the month, plus statistical tables, charts, and technical notes. $4 ($25 per year).

Current Wage Developments. Each issue includes selected wage and benefit changes, work stoppages, and statistics on compensation changes. $2 ($21 per year).

Employment and Earnings. Each issue covers employment and unemployment developments in the month plus statistical tables on national, State, and area employment, hours, and earnings. $4.50 ($31 per year).

Occupational Outlook Quarterly. Each issue helps people planning careers, guidance counselors, and others keep informed of changing career opportunities. $3 ($11 per year).

Producer Price Indexes. Each issue includes a comprehensive report on price movements for the month plus regular tables and technical notes. $4.25 ($29 per year).

IN THE MAZE OF ECONOMIC AND SOCIAL STATISTICS,

do you sometimes feel like Stanley hunting for Livingstone?

If so, your search for a single source of reliable and comprehensive statistics and analysis is over. Subscribe to the MONTHLY LABOR REVIEW, the oldest government journal providing up-to-date information on economic and social statistics.

PUBLISHED CONTINUOUSLY SINCE 1915, the REVIEW provides a 48-page section of current statistics covering employment and unemployment; wages and strike activity; worker and capital productivity; unit labor costs and output; consumer, industrial, and international prices; economic growth; and related topics. Each month, the REVIEW also contains articles and informative reports. Some recent titles are:

- Job Training Partnership Act
- Older workers in the labor market
- Japan's low unemployment
- Employee-owned firms
- The labor force in 1995
- Multifactor productivity
- Import prices for petroleum
- The employment cost index
- Work injuries from falls
- Youth joblessness
- Men's and women's earnings
- Occupational winners and losers
- Black workers' gains
- Shortage of machinists?
- Price inflation remains low
- Employment in energy industries
- Collective bargaining
- Fatal injuries

MONTHLY LABOR REVIEW

SEPTEMBER 1986
VOLUME 109, NUMBER 9

Henry Lowenstern, Editor-in-Chief
Robert W. Fisher, Executive Editor

Robert N. Frumkin 3 **Health insurance trends in cost control and coverage**
Between 1979 and 1984, companies often moved to curb rising health plan expenditures, in some cases, increasing the cost to employees, but benefit improvements continued

M. E. Einstein, J. C. Franklin 9 **Computer manufacturing enters a new era of growth**
Strong gains in output and employment are estimated to 1995; not surprisingly, expansion is not projected to rival the extraordinary pace the industry set during the last 25 years

S. Danziger, P. Gottschalk 17 **Work, poverty, and the working poor: a multifaceted problem**
New study shows that most able-bodied household heads demonstrate a strong attachment to the labor force, but their employment tends to be intermittent, low-paying, or both

P. J. McMahon, J. H. Tschetter 22 **The declining middle class: a further analysis**
For all population groups, the proportion of employment in higher paying occupations increased during 1973-82; the earnings distribution of these occupations also shifted

Labor Month In Review

A VIEW OF THE 80'S. The Congressional Research Service of the Library of Congress reported to the Congress on employment trends in the 1980's from a national, industrial, and regional perspective. The report, based in large part on BLS data, was prepared by Linda LeGrande and Mark Jickling. Excerpts:

National trends. The first two-thirds of the 1980's can be divided into 2 distinct periods. The earlier years are marked by two recessions. The economy barely had an opportunity to recover from the January-July 1980 downturn before it was hit by the much more severe and protracted July 1981-November 1982 recession.

While overall employment headed downward between 1979 and 1982, service sector jobs rose by 3.8 percent, or 2.4 million. Once the economy began its recovery, job growth in the sector became more robust: 6.9 million jobs were added, producing a 10.5-percent rate of gain.

The performance of the goods-producing sector contrasts sharply with that of the service-producing sector. The goods sector lost 2.6 million or 10 percent of its jobs between 1979 and 1982. Some 85 percent of the cutbacks occurred in manufacturing, with durable goods producers accounting for three-fourths of the lost manufacturing jobs.

Between 1982 and 1985, total employment in the goods-producing sector rebounded. It regained 47 percent (1.2 million) of the jobs lost during the recession period. Most of the sector's components expanded employment. However, the mining industry, which actually increased employment during the two recessions, cut its work force between 1982 and 1985.

Despite the relatively good economic climate and employment gains of the past few years, total employment in the goods-producing sector in 1985 was 1.4 million jobs (5.3 percent) below its 1979 level. Some of the industries having smaller work forces in 1985 than in 1979 may eventually return to their prerecession size. Other industries with fewer jobs at mid-decade may be undergoing a structural transformation from which they might emerge with permanently smaller work forces.

Regional trends. Five of the nine regions actually reported increased total nonfarm employment during the two recessions: West South Central (9.5 percent) Mountain (3.9 percent), South Atlantic (3.1 percent), and Pacific and New England (1 percent each).

The East North Central bore the brunt of the recessions' impact; 8.1 percent of the region's nonfarm jobs disappeared. The East South Central and West North Central regions experienced job losses of 4.9 percent and 4.2 percent, respectively. The economic downturn had much less of an influence in the Middle Atlantic region, where employment fell less than 1 percent.

Regional nonfarm employment rebounded across the board between 1982 and 1985. Most regions that reported employment gains during the recession period grew at a faster rate, however, than the four regions that were adversely affected by the downturn of the business cycle.

While only the West South Central and Middle Atlantic regions recorded manufacturing job losses during both the recovery and recession periods, manufacturing employment in four other regions—New England, East South Central, and East and West North Central—failed to rebound enough between 1982 and 1985 to reach or surpass its prerecession level.

Economic diversification. Given the relative imperviousness of the service-producing *vis-a-vis* the goods-producing sector to the ups and downs of the business cycle, one might argue that States should target their economic development efforts toward business and professional service firms, banks and insurance companies, consumer-oriented enterprises, and the like. Given the relatively better performance of high tech *vis-a-vis* smokestack manufacturing industries during the 1980's recessions, one might argue that States should encourage the expansion of already existing high tech firms within their borders and the (re)location of new high tech firms to their towns.

However, today's high-flying industry may be tomorrow's problem-plagued industry. In addition, high tech manufacturing cannot be every State's solution, because it is expected to continue to contribute only a small share of future new jobs. Moreover, some States may be better able than others to alter their industrial mix. To attract different industries, a State must have or be able to provide the requisite infrastructure for them.

To assist those States that choose to change their industrial structures, the Federal Government might act as an information clearinghouse. In such a capacity, a government agency could collect and disseminate case studies of various areas' experiences with economic diversification. States then might more easily study the issue before proceeding and perhaps be able to avoid problems encountered elsewhere during their diversification efforts. In addition, the Government could provide States with information concerning any financial resources available to them in their development activities.

Economic diversification is desirable if one's goal is to moderate employment fluctuations. It is not a panacea, however. Some States may be better able than others to change their industrial mix. Some States may want to consider using other adjustment measures in combination with diversification to mitigate the effects of the transition process on certain industries and their workers. □

Health insurance trends in cost control and coverage

An analysis of changes in company health plans between 1979 and 1984 shows that employers often sought to contain rising expenditures, in some cases, increasing the cost to workers; improvements in benefits, however, continued

ROBERT N. FRUMKIN

Influenced by rapidly rising costs of health care, companies often raised their employees' share of the total health care bill and also modified plans to encourage use of less costly health services during the 1979–84 period. At the same time, however, some health plans improved benefit features, such as increasing the maximum lifetime payments under major medical plans.

Although cost containment efforts and benefit improvements were common, approaches to achieve these objectives varied. To analyze these efforts, the Bureau of Labor Statistics traced provisions of 209 employee health plans for the 1979–84 period.

These plans were found in 173 establishments and covered at least 1.8 million workers.[1] The plans were mainly those of large companies, with 61 percent covering 1,000 workers or more (6 percent of the plans covered at least 25,000). While clearly not a representative sample of all health insurance plans, they do cover a substantial number of both union and nonunion workers, and offer insights into plan provisions over the 5 years studied. All but 11 of the health plans changed at least one of the features reviewed in this article between 1979 and 1984.

The 209 plans analyzed in this article comprise all plans common to both the 1979 and 1984 Bureau of Labor Statistics Employee Benefits Surveys. This annual survey provides data on the incidence and detailed provisions of benefit plans financed at least partially by medium and large companies. Under health plans, the survey covers provisions for hospital, surgical, medical, major medical, extended care, and other benefits. It also looks at methods of funding benefits (but not actual employer costs) and the incidence and amounts of employee contributions for individual and family coverage.[2]

Measures taken

Efforts to curb costs stemmed from rapid increases in health care outlays. Total national health expenditures rose from $215.1 billion in 1979 to $387.4 billion 5 years later.[3] This increase reflects both the introduction of new and expensive treatments for many illnesses and a sharp rise in prices for health services. Over the 1979–84 period, the medical care component of the Consumer Price Index rose at a 9.6-percent annual rate, compared with 7.4 percent for the index as a whole. Such cost increases helped to drive up employer financing of group health insurance, from $51.3 billion in 1979 to $96.9 billion in 1984.[4]

Cost containment measures took many forms. Quite noticeable were actions that increased the worker's share of health care costs. For example, a number of the plans were redesigned to eliminate basic coverage for certain types of care and transfer payment arrangements entirely under a major medical plan. (See table 1.) Basic plans, applying to an individual category of care—hospital, surgical, or medical—typically provide "first-dollar" coverage; that is, an insured individual is not required to make an initial payment for care.

Robert N. Frumkin is an economist in the Division of Occupational Pay and Employee Benefit Levels, Bureau of Labor Statistics.

Conversely, major medical plans—which cover several categories of expenses—eliminate "first-dollar" coverage and require cost-sharing by the employee through deductibles and coinsurance provisions. A deductible is a specified amount an insured individual must pay toward health care expenses before any benefits are provided by the plan. Slightly more than one-fifth of the plans increased the size of the deductible in existing major medical insurance policies between 1979 and 1984. Expenses in excess of the deductible are shared by the individual and the insurance plan on the basis of a specified coinsurance rate; plans typically pay 80 percent of covered charges, while the insured pays the remaining 20 percent.

Table 1. Summary of changes in 209 health insurance plans, 1979 and 1984

Change	Number of plans changed	Percent of plans changed
Cost containment		
Basic coverage eliminated for:		
Hospital benefits	27	12.9
Surgical benefits	28	13.4
Medical benefits	23	11.0
Diagnostic x ray and laboratory benefits	21	10.0
Major medical plans:		
Increased deductible	46	22.0
Increased employee's coinsurance payments	4	1.9
Increased maximum limits on employee's expenses	9	4.3
Eliminated maximum limit on employee's expenses	1	.5
Decreased lifetime maximum benefit	7	3.3
Converted to self-insured plan	38	18.2
Converted to partly insured and partly self-insured plan	16	7.7
Converted to comprehensive major medical plan	26	12.4
Reduced first dollar coverage	4	1.9
Added extended care facility benefit[1]	34	16.3
Added home health care benefit[1]	62	29.7
Employee-paid premiums increased or added:		
For employee coverage	30	14.4
For family coverage	68	32.5
Coverage improvements		
Basic hospital benefits:		
Increased duration	18	8.6
Increased daily payments	16	7.7
Basic surgical benefits:		
Increased maximum scheduled allowance	30	14.4
Added full coverage for outpatient care	17	8.1
Basic medical benefits:[2]		
Increased duration	8	3.8
Increased payment per visit	25	12.0
Added payment for office visit	7	3.3
Diagnostic x ray and laboratory benefits:		
Raised ceiling on annual payments	74	35.4
Major medical benefits:		
Decreased deductible	12	5.7
Decreased employee's coinsurance payments	9	4.3
Decreased maximum limits on employee's expenses	25	12.0
Introduced maximum limit on employee's expenses	42	20.1
Increased lifetime maximum benefit	118	56.5
Added benefits	8	3.8
Increased first dollar coverage	14	6.7
Employee-paid premiums reduced or eliminated:		
For employee coverage	16	7.7
For family coverage	22	10.5

[1] Also a coverage improvement.

[2] Includes payments for treatment in hospital and in physician's office.

Some employers also modified their approach to funding benefits. They substituted, either completely or partially, self-funding for the purchase of a health insurance policy from a commercial insurance company, such as Aetna, or an association of hospitals or physicians (Blue Cross-Blue Shield). Employers who insure their own benefits have greater control over plan design and, therefore, can control costs more directly. Growth in this type of funding was most pronounced for major medical benefits, for which the number of self-insured plans more than doubled—from 27 in 1979 to 65 in 1984. (See table 2.) Nevertheless, commercial insurance continued to be the most common method of funding both basic and major medical insurance benefits in 1984.

Still another form of cost containment provided alternatives to care in a hospital. Thirty-four of the plans added coverage for expenses in an extended care facility, such as noncustodial care in a nursing home, and 62 introduced home health care benefits.

Spurred by the passage of the Health Maintenance Organization Act of 1973, more employers have offered the choice of an HMO as an alternative to other health insurance benefits.[5] Usually providing comprehensive health care at a fixed fee, Health Maintenance Organizations have been viewed as a possible lower cost alternative to other health care. These organizations encourage preventative medicine and have lower hospitalization rates for their members. There were 11 HMOs among the 209 plans in both 1979 and 1984.

Changes in benefit financing also affected employees. In both years of this study, the majority of the plans examined were noncontributory, that is, employers paid all of the insurance premiums. The following tabulation shows, however, that in the jointly financed plans, the amount of employee contributions nearly doubled from 1979 to 1984.

	Number of plans		*Average employee monthly contribution*	
	1979	*1984*	*1979*	*1984*
Jointly financed coverage:				
Employee	61	67	$ 6.43	$11.57
Family	100	92	17.07	33.22

Although cost containment efforts attracted most attention, benefit improvements were not ignored between 1979 and 1984, particularly in the area of major medical benefits. Slightly more than half the 209 plans studied increased maximum lifetime benefits under major medical provisions, and 67 improved financial protection against catastrophic illnesses by either introducing a ceiling on employees' "out-of-pocket" expenses (42 plans) or lowering an existing ceiling (25 plans). A third of the plans raised maximum annual payments for diagnostic x ray and laboratory benefits. Table 1 shows the frequency of a variety of other health insurance coverage improvements.

Table 2. Funding media for selected types of coverage in 209 health insurance plans, 1979 and 1984

Funding media	Basic hospital[1]		Basic surgical[1]		Basic medical[1]		Major medical[2]	
	1979	1984	1979	1984	1979	1984	1979	1984
Total	209	209	209	209	209	209	209	209
Coverage provided	187	161	165	156	126	115	186	194
Blue Cross-Blue Shield	53	49	45	37	44	36	20	27
Commercial carrier	99	61	88	68	58	43	139	102
Independent health plans	35	51	32	51	24	36	27	65
Labor/management[3]	24	40	21	40	13	25	27	65
Health Maintenance Organization[4]	11	11	11	11	11	11	–	–
Coverage not provided	22	48	44	53	83	94	23	15

[1] Basic benefits apply to individual categories of expenses such as hospital, surgical, or medical expenses. They generally apply without deductible or coinsurance provisions.

[2] Major medical benefits cover many categories of expenses, some of which are not covered under basic benefits, and others for which basic coverage limits have been exhausted. Major medical benefits are characterized by deductible and coinsurance provisions that are applied across categories of care.

[3] Includes plans that are financed by general revenues of a company on a pay-as-you-go basis, plans financed through contributions to a trust fund established to pay benefits, and plans operating their own facilities if at least partially financed by employer contributions. Includes plans that are administered by a commercial carrier through Administrative Services Only contracts.

[4] Includes federally qualified (those meeting standards of the Health Maintenance Organization Act of 1973, as amended) and other HMOs delivering comprehensive health care on a prepayment rather than fee-for-service basis. All HMOs are included here regardless of sponsorship, for example, Blue Cross-Blue Shield or a commercial insurance carrier.

NOTE: Dash indicates no plans in this category.

The following sections of this article explore the interplay between cost containment and benefit improvements as found in individual health insurance areas.

Hospital benefits

The average expense for a day of hospital care increased from $217 in 1979 to $411 in 1984, according to the American Hospital Association.[6] Over this period, more employees were required to share in the cost if hospitalized. For example, 27 of the 209 plans studied adopted this requirement by eliminating basic coverage. This raised the number of plans studied with only major medical coverage for hospitalization from 22 to 48. (See table 3.)

Also, more employees with basic hospital benefits were required to pay a deductible before their confinements were covered. In 1984, 17 of the plans imposed a deductible, compared with 12 plans in 1979. The type of deductible varied from no benefit coverage for the first day in the hospital to a specified dollar amount. The most common deductible was $100 for the first day in the hospital.

The average daily cost for a semiprivate room rose from $134 in 1979 to $209 in 1984.[7] As in 1979, most plans in 1984 based payment for a hospital confinement on the semiprivate room rate, automatically allowing benefit levels to keep pace with inflation. Roughly 10 percent of the plans in both years paid a cash room-and-board allowance, for a daily average of $68 in 1979 and $113 in 1984.

Eighteen of the plans increased the maximum duration of hospital coverage. At least half of the plans, 68 in 1979 and 62 in 1984, provided hospital benefits for 365 days or more; nearly all plans covered at least 70 days.

Extended care benefits

To counter the sharp rise in hospital costs, benefit provisions for medical care outside hospitals are becoming more prominent. Benefits may cover medical treatment at an extended care facility or at home, both less costly than long-term hospitalization. As noted, a day's cost for hospitalization averaged $411 in 1984, compared with $150 for confinement in an extended care facility and $40 for home care.[8]

The potential cost advantages of alternative health care over hospitalization prompted a net increase in the number of plans providing coverage for extended care facility (28 plans) and home care (59). (See table 4.) Two-fifths of the plans covering extended care facilities in 1979 modified their terms by 1984, changing either a benefit provision (such as duration or dollar amount of coverage) or type of coverage (such as converting from major medical to basic benefits), or both. Extended care benefits commonly are available only after hospitalization, however.

Surgical benefits

Cost containment also affected surgical benefits. Twenty-eight of the plans eliminated first-dollar coverage for surgery in 1984. (See table 1.) Also, as an incentive to reduce costs, 17 plans with deductibles or coinsurance, or both, for surgery performed on an inpatient basis offered full payment for surgery performed on an outpatient basis.

In 1984, 153 of the plans paid all or a percent of the "usual, customary, and reasonable" charges for surgical procedures, up 14 plans from 1979.[9] This approach automatically links benefit levels to rising costs. The remaining 56 plans specified cash allowances for covered surgical procedures; of these, 30 had increased the allowance after 1979, raising the average allowance for the most expensive covered procedure from $925 to $1,400.

Medical benefits

One plan in the study added in-hospital medical benefits after 1979, resulting in all having this benefit by 1984. Ninety-four plans, up from 82 in 1979, covered in-hospital medical visits under major medical benefits only; consequently, they did not provide first-dollar coverage. (See table 3.) Payments were based on usual, customary, and reasonable arrangements in 171 plans, 11 more than in 1979. Visits to a physician's office were covered by 206 plans in 1984, up 6 plans from 1979. Coverage for 1984 was through major medical benefits in 171 plans and through combined basic and major medical benefits in 21. All major medical arrangements were on a usual, customary, and reasonable basis.

In 1984, 16 plans included some form of cost sharing other than a general deductible or coinsurance requirement for visits to a doctor's office, up 5 plans from 1979. Devices ranged from co-payments by the insured of from $1 to $10 per visit to no payment by the insurance plan for the first visit or a specified number of visits. Employee co-payments were generally associated with Health Maintenance Organizations, with the most common being $2 per visit.

Diagnostic x ray and laboratory benefits

All of the health insurance plans in the study provided diagnostic x ray and laboratory benefits in both 1979 and 1984. However, the number of plans providing this service through both basic and major medical benefits declined from 144 to 93; 28 additional plans provided this service through basic benefits only in 1984, and 23 provided it through major medical benefits only. (See table 3.)

Plans usually paid for diagnostic care on a usual, customary, and reasonable basis in both years. Of the 60 plans designating cash allowances in 1984, 34 had increased scheduled payments for this service over the 5 years studied; consequently, the average maximum allowance increased from $175 to $310 per year. If diagnostic care were done on an outpatient basis, 63 plans paid the full cost in 1984, compared with 35 plans in 1979.

Major medical benefits

All but 15 of the plans studied provided major medical benefits in 1984; 23 plans did not provide this benefit in 1979. The 11 Health Maintenance Organizations by their nature preclude separate major medical provisions and the remaining four plans provided basic benefits only, but were sufficiently comprehensive to counter the need for a separate major medical plan. Changes that reduced costs or improved benefits were made more often to major medical provisions than to any other health benefit examined.[10]

Major medical plans typically include two cost-sharing features—deductibles and coinsurance requirements. All but two of the major medical plans in 1984 called for a deductible, as did all such plans studied in 1979. Deductibles were typically established on a yearly basis and were commonly $100 per person in 1979 and 1984. By 1984, however, 41 plans required more than $100, compared with 16 plans in 1979. Also, four plans changed to a deductible of 1 percent of earnings. Previously, two of these plans had a deductible of $50 and two, a deductible of $100.

There are two types of major medical insurance: supplemental and comprehensive. Supplemental benefits provide additional coverage to the separate basic plans. Comprehensive plans stand alone and combine the types of benefits found in basic and major medical plans. Because comprehensives eliminate nearly all first-dollar coverage, they offer greater savings opportunities in insurance premiums than basic/supplemental plans. From 1979 to 1984, the number of comprehensive plans in the study nearly doubled, from 31 to 57 plans.

Coinsurance provisions were found in all of the major medical plans studied in both years. The coinsurance rate paid by the plans, most commonly 80 percent, changed very little during this period. In 1984, 20 of 194 major medical plans paid more than 80 percent of the health care expenses, while one plan paid less; this compared with 16 and none, in 1979.

A significant improvement in major medical benefits was adding financial protection against catastrophic illnesses. This provision limits the yearly "out-of-pocket" expenses an insured individual must pay. It was part of 156 plans in 1984, compared with 106 in 1979. In both years, the majority of plans set the limit at $1,000 a year.

Maximum benefits payable under a major medical plan are specified on a per disability or, more commonly, on a lifetime basis. In 1979 and 1984, the most common lifetime maximum benefit was $250,000 among the plans studied. Since 1979, however, 118 plans raised their benefit ceilings, while eight eliminated them entirely. The results are as follows:

Table 3. Distribution of 209 health insurance plans by benefit arrangement for selected categories of care, 1979 and 1984

Category	Benefit arrangement							
	Basic benefit only		Major medical benefit only		Basic and major medical benefits		Care not provided	
	1979	1984	1979	1984	1979	1984	1979	1984
Hospital care	41	34	22	48	146	127	–	–
Extended care facility	46	56	39	58	20	19	104	76
Home health care	23	51	10	37	7	12	169	109
Surgical care	74	70	44	53	91	86	–	–
Medical care-in hospital	32	22	82	94	94	93	1	–
Medical care-office visit	15	14	165	171	20	21	9	3
Diagnostic x ray and laboratory benefit	40	68	25	48	144	93	–	–

[1] Basic benefits apply to individual categories of expenses, such as hospital, surgical, or medical expenses. They generally apply without deductible or coinsurance provisions.

[2] Major medical benefits cover many categories of expenses, some of which are not covered under basic benefits, and others for which basic coverage limits have been exhausted. Major medical benefits are characterized by deductible and coinsurance provisions that are applied across categories of care.

NOTE: A given plan may offer categories of care under different types of payment, for example, hospital care as a benefit (typically no initial payment by the employee), visits to a physician's office as major medical benefit (cost shared by employer and employee), and surgical care as first a basic benefit and then as a major medical benefit. Dash indicates no plans in this category.

Table 4. Extended care benefit changes in 209 health insurance plans, 1979 and 1984

Action taken by 1984	Extended care facility		Home health care[1]	
	Number of plans	Percent of plans	Number of plans	Percent of plans
Total	209	100.0	209	100.0
Added benefit	34	16.3	62	29.7
Eliminated benefit	6	2.9	3	1.4
Changes in existing benefits[2]	44	21.1	14	6.7
Basic benefits provision[2]	30	14.4	9	4.3
Duration	15	7.2	8	3.8
Dollar amount	14	6.7	1	.5
Other[3]	3	1.4	–	–
Changes in type of coverage	21	10.0	8	3.8
From basic only to major medical only	4	1.9	–	–
From basic only to basic and major medical	2	1.0	1	.5
From major medical only to basic only	6	2.9	3	1.4
From major medical only to basic and major medical	1	.5	1	.5
From basic and major medical to basic only	2	1.0	1	.5
From basic and major medical to major medical only	6	2.9	2	1.0
Benefit unchanged	49	23.4	21	10.0
No benefit in either year	76	36.4	109	52.2

[1] Includes care provided by a Visiting Nurse Association and related benefits.

[2] The total is less than the sum of the individual items because more than one change may have occurred for one benefit.

[3] Includes an addition of a basic benefits deductible, elimination of a copayment, and a change from a first-dollar coverage to a limit on the number of days covered.

NOTE: Dash indicates no plans in this category.

	1979	1984
Plans with maximum lifetime benefits	156	156
Below $250,000	86	36
$250,000	58	55
Above $250,000	12	65
Plans with unlimited lifetime benefits	30	38
Average lifetime maximum benefit	$193,000	$450,000

Other health benefits

Other health insurance benefits examined in this study included provisions for mental health care, prescription drugs, private duty nursing, dental care, and vision care. As the following tabulation shows, mental health care, prescription drugs, and private duty nursing were found in 95 percent or more of the plans. Dental coverage was prevalent in 1979 and showed substantial growth by 1984, but vision care continued to be covered in a minority of the plans.

Coverage	1979	1984
Number of plans with—		
Mental health	208	209
Basic benefits only	26	19
Major medical only	24	50
Basic and major medical	158	140
Prescription drug	205	204
Basic benefits only	29	25
Major medical only	170	170
Basic and major medical	6	9
Private duty nursing	199	203
Basic benefits only	15	7
Major medical only	181	192
Basic and major medical	3	4
Dental	116	173
Vision care	53	62

Major medical plans, rather than basic plans, generally provide coverage for private duty nursing and prescription drug care. Both dental and vision care benefits were provided either as part of a comprehensive health insurance package or as a free-standing plan. In nearly all cases, dental benefits entailed a deductible separate from that for other health benefits, and covered at least a portion of usual, customary, and reasonable charges, or provided scheduled cash allowances.

New ways to cut costs

Aside from revising plan provisions, such as increasing major medical deductibles, cost containment efforts have promoted new types of features. None was in a majority of the plans studied in 1984, and because of their relative rarity at the time, these features were not analyzed in 1979. The following tabulation shows the number and percent of plans with a specific cost-containment provision:

	Number	Percent
Second opinion provision before elective surgery	91	44
Higher rate of payment for testing prior to hospital admission	86	41
Hospice care	22	10
Routine physical examination	17	8
Higher rate of payment for generic drugs	7	3
Reduced or no plan coverage for nonemergency weekend hospital admissions	6	3

Cost containment efforts go beyond the provisions considered in this article. Incentives for use of preferred provider organizations, intensified claims review procedures, and introduction of health education and health promotion ("wellness") plans are other approaches that have emerged recently to halt rising health care costs. These items, however, are beyond the current scope of the Bureau's Employee Benefits Survey.[11] □

——FOOTNOTES——

[1] The number of plans exceeds the number of establishments because some establishments maintained more than one plan, either giving employees a choice of plans or providing dictinct plans for different employee groups. The total number of workers covered by the 209 plans is unknown because some of the plans were in multi-establishment companies and covered employees in units other than those surveyed. The employment figure cited in the text reflects plan participation in surveyed establishments only.

[2] Survey results are published in an annual BLS bulletin and special analyses of individual benefit areas, such as health insurance and retirement plans, are featured periodically in the *Monthly Labor Review*.

The survey covers, on a sample basis, private sector establishments in the United States, excluding Alaska and Hawaii, employing at least 50, 100, or 250 workers, depending on the industry. Industrial coverage includes: mining; construction; manufacturing; transportation, communications, electric, gas, and sanitary services; wholesale trade; retail trade; finance, insurance, and real estate; and selected services. The survey analyzes benefit plans paid for wholly or partly by employers; benefits financed entirely by employees are excluded. Findings for 1984 are reported in *Employee Benefits in Medium and Large Firms*, Bulletin 2237 (Bureau of Labor Statistics, 1985). For information on the background and conduct of the survey, see Robert Frumkin and William Wiatrowski, "Bureau of Labor Statistics takes a new look at employee benefits," *Monthly Labor Review*, August 1982, pp. 41–45.

O'Brien, "Health Care Cost Containment: An Employer's Perspective," *Labor Law Journal*, August 1985, pp. 468–73; Karen Ignagni, "Organized Labor's Perspective on Rising Health Costs," *Labor Law Journal*, August 1985, pp. 473–76; William G. Williams, "Health Care Cost-Containment Techniques," in Jerry S. Rosenbloom, ed., *The Handbook of Employee Benefits* (Homewood, Il., Dow Jones-Irwin, 1984), pp. 251–72; and *World of Work Report*, November 1985, pp. 1–2.

A note on communications

The *Monthly Labor Review* welcomes communications that supplement, challenge, or expand on research published in its pages. To be considered for publication, communications should be factual and analytical, not polemical in tone. Communications should be addressed to the Editor-in-Chief, *Monthly Labor Review*, Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

Computer manufacturing enters a new era of growth

Strong gains in output and employment are estimated to 1995; not surprisingly, the most optimistic of three projections does not match the extraordinary pace the industry has set in the last 25 years

Marcus E. Einstein and James C. Franklin

From the early 1960's through the mid-1980's, the outlook for growth in the computer manufacturing industry was, for most of the period, unusually optimistic. Even the 1981–82 recession seemed to have little effect on the industry's growth. In 1985, however, the outlook for the industry clouded considerably. Business demand for computers fell, as well as the demand for home computers. Some companies reported huge losses, and several went bankrupt. Even firms in Silicon Valley, an important center for computer manufacturing, laid off workers. The industry is now apparently at a turning point, entering an era of slower growth.

To provide some insights into the current situation, the Bureau of Labor Statistics undertook a study that focused on the development of alternative projections of industry output and employment. This article presents the results of that study.

For several decades, the Bureau of Labor Statistics has developed projections of the U.S. economy under alternative sets of assumptions. The latest set of three projections, to 1995, were published in the November issue of the *Monthly Labor Review.*[1] These and previous BLS projections were based on alternative macroeconomic assumptions, such as the unemployment rate, productivity growth, and labor force growth. While the projections for the computer manufacturing industry presented in this study reflect the recent economic projections, industry alternatives that assume different circumstances regarding the pace of technological development in the industry are also explored.

The results of this study are based on the assumption that although significant technological advances will be forthcoming during the projection period, none will have the dramatic impact of the introduction of the minicomputer in the mid-1960's or the microcomputer in the mid- to late 1970's. The analysis shows rates of projected growth of both output and employment varying significantly under the alternative scenarios. In all scenarios, the growth rate for the computer manufacturing industry is projected to exceed the average for the economy as a whole and to have one of the highest growth rates among manufacturing industries. However, the highest projected growth rate is still below that experienced over the past decades. This should come as no surprise given the rapid expansion of the industry and its present size.

Historical overview

Over the last 25 years, the computer and peripheral equipment manufacturing industry (SIC 3573-4)[2] has been one of the more dynamic and fastest-growing industries in the U.S. economy. Industry products represented more than 20 percent of all business investment in 1984, and computers are one of the few manufacturing industries in which the United States still shows a sizable world trade surplus, estimated at $6.8 billion in 1985.[3] In addition, computers recently have become a factor in purchases of goods by households. Virtually nonexistent in 1975, personal computers are now estimated to be in 10 percent of households. Employment growth in the computer manufacturing industry has also played an increasingly more important role in the economy. With employment growth averaging more than 6 percent annually from 1960 through 1984, the industry has been adding new jobs at a rate 10 times faster than for all manufacturing.

Marcus E. Einstein and James C. Franklin are economists in the Office of Economic Growth and Employment Projections, Bureau of Labor Statistics.

Technological development. The development of the computer manufacturing industry can be traced, in part, through a continuous stream of technological breakthroughs in computer engineering. These advances, primarily in the area of miniaturization, have transformed the computer from a "30-ton" monster to a 2- or 3-pound machine small enough to sit comfortably on a person's lap.

Prior to 1965, the industry primarily produced large mainframe computing systems. Annual unit sales grew on average by 33 percent between 1960 and 1964. (See table 1.) Because of the size and expense of these systems, most buyers or lessees were large institutions, such as banks, insurance companies, or government agencies.

The still young industry recognized the potential demand for a smaller and less expensive system than the mainframe. This led to the development of the minicomputer. Introduced in 1965, the "minis" were very well received and for the next 10 years annual unit sales increased on average by 50 percent. (See table 1.) However, because minicomputers were much cheaper, the dollar value of sales grew less rapidly, at an average annual rate of about 10 percent.

Increased miniaturization, declining component costs, and other technical developments led to the introduction of the personal computer in 1975. Initially developed by enterprising computer engineers and sold in kits via mail order, the personal computer since has become the dominant product of the industry in terms of unit sales, accounting for more than 96 percent of domestic consumption for all computers. Over the 1975–84 period, annual growth in unit sales of the personal computer averaged 95 percent. On a value basis, however, personal computers represent only 35 percent of industry sales because the unit prices of personal computers are much lower.

Capital expenditures. Throughout the 1960's, business investment in computer equipment grew 10 percent a year, on average, or at roughly the same rate as overall capital investment. Purchases of computer equipment represented, on average, a relatively constant 3 to 4 percent of all capital expenditures. However, beginning about 1970, businesses started to devote more of their investment dollars to computerizing their operations and, as a result, the share of total business investment expenditures attributed to computers grew to 9.6 percent in 1979. (See table 2.)

Emerging from the high inflation period of the 1970's, marked by increased labor costs and increased competition from abroad, American industry began searching for a means to increase productivity by modernizing plants and

Table 1. Domestic consumption of micro, mini, and mainframe computers,[1] 1960–84
[Dollars in millions]

[1] Micro, mini, and mainframe are defined in terms of price: micro–$1,000 to $19,999; mini–$20,000 to $249,999; mainframe–$250,000 and over.

NOTE: Because microcomputers exclude units with list prices less than $1,000, the sales of most personal home computers are not reflected in these figures.

SOURCE: Computer and Business Equipment Manufacturers Association.

curtailing labor costs. The computer manufacturing industry encouraged increased use and extended applications of the computer as one possible solution. Manufacturers began offering microcomputers that were built with mass-produced microprocessors and invited anyone who was interested to write the software. The result for the computer buyer was hardware and software that were both more adaptable and less expensive than the minicomputer. Aided further by changes in the tax treatment for capital expenditures in the Economic Recovery Tax Act of 1981, businesses generally responded by increasing capital spending and by devoting a larger share to computers. Business investment in computers surged over the 1980–84 period and increased from 12 percent of total investment in 1980 to more than 20 percent in 1984. (See table 2.)

Foreign trade. America's early lead in computer technology allowed U.S. manufacturers to dominate world markets during most of the 1970's. U.S. exports of computers grew from $1.3 billion in 1972 to more than $4 billion in 1978 (both stated in current prices). In the late 1970's, imports began to appear in U.S. markets. However, despite foreign competition, the computer industry's trade balance continued to grow, peaking in 1981 at $7 billion.

Since 1981, however, trade surpluses have been declining steadily, in part because of competition from East Asian and Pacific Basin countries. As a result of a number of factors, including intense price competition, many U.S. computer manufacturing companies moved their production operations to the Far East, including Singapore and Hong Kong, which offered government incentives for local investment and lower labor and materials costs. In addition, the Japanese entered the world market using the high-volume, price-cutting techniques which they had successfully used in other electronic product markets. In 1984, however, the U.S. computer industry still had a trade surplus of $5.9 billion, as shown below (millions in current dollars):[4]

Year	*Exports*	*Imports*	*Trade balance*
1977	$ 3,264	$ 253	$3,011
1978	4,129	757	3,372
1979	5,500	969	4,531
1980	7,606	1,159	6,447
1981	8,652	1,647	7,005
1982	9,118	2,296	6,822
1983	10,569	4,362	6,207
1984	13,511	7,575	5,936

Personal consumption. The history of the home segment of the computer industry is short, spanning only the last 10 years. As noted, the first home, or personal, computers were produced about 1975. They came in kit form and were sold mostly to hobbyists. Fueled by technological improvements, plummeting prices, and widespread interest and publicity about computers, home computer sales grew rapidly from around 210,000 units in 1978 to more than 5 million machines in 1984.[5] This growth slackened recently and is a factor in bringing the computer industry to an important juncture—posing the prospect for much slower growth in the future than experienced over most of the last 25 years. Many initial buyers may have been caught up in the "faddish" element of the computer revolution and perhaps initially did not fully understand the limitations of the machines and the difficulties of use. As skepticism grew and price wars accelerated, consumers apparently began to delay purchases, waiting for even lower prices, for more user-friendly software, and simpler and easier to use machines.

Table 2. Purchases of producers' durable equipment, 1960–84

[1977 dollars in billions]

Year	Total business investment	Business investment, in office, computing, and accounting machinery[1]	Computing equipment as percent of total
1960	53.4	1.5	2.8
1961	52.1	1.4	2.7
1962	57.6	1.4	2.4
1963	61.6	1.8	2.9
1964	68.9	2.0	2.9
1965	80.9	2.3	2.8
1966	91.9	3.1	3.4
1967	90.7	3.2	3.5
1968	95.3	3.2	3.4
1969	102.6	4.0	3.9
1970	100.0	4.0	4.0
1971	99.4	4.0	4.0
1972	110.4	4.9	4.4
1973	130.1	5.7	4.4
1974	132.0	7.0	5.3
1975	116.4	6.4	5.5
1976	123.7	8.1	6.5
1977	143.1	10.0	7.0
1978	162.8	13.0	8.0
1979	173.0	16.7	9.6
1980	167.7	20.2	12.0
1981	174.4	25.8	14.8
1982	162.6	29.4	18.1
1983	174.4	34.3	20.2
1984	209.9	43.5	20.7

Employment. The computer manufacturing industry has also experienced dramatic changes in employment. From 1960 through 1984, employment growth averaged more than 6 percent annually, while employment growth for all of manufacturing averaged only 0.6 percent. As a consequence, computer manufacturing accounted for nearly 14 percent of the growth in wage and salary employment in manufacturing over the 1960–84 period, although in 1984 it still represented less than 2.5 percent of all manufacturing jobs. (See table 3.)

Although overall employment in the computer manufacturing industry has been increasing, the percentage of employees in production occupations has been declining. In the mid-1960's, when the industry was producing mainframe and minicomputer systems, production worker employment was as high as 47 percent of the total. However, the ratio steadily declined with a growing emphasis on research and development activities, expanding at a rate of almost 18 percent annually, along with continuing automation of the production line. A slight resurgence in production employment occurred in the first few years of the personal computer. As new companies entered the market at a rapid pace, production workers were actually increasing faster than overall industry employment, reaching 41 percent of industry employment in 1979. Since then, growth in production-related occupations has slowed owing to the concentration on research and development expenses, increased automation of the production line, and the movement offshore of production facilities.

Currently, more than 25 percent of employment in the computer manufacturing industry consists of engineers, technicians, and systems analysts. The relatively high concentration of these occupations can be explained by the high priority of research and development operations. In 1983–84, computer manufacturers spent more than $6 billion on R&D activities, representing more than 7 percent of sales.[6]

In contrast to the high percentage of engineers, technicians, and computer analysts employed in the computer manufacturing industry, only 38 percent of all employees were in production-related occupations in 1984. This is one of the lowest ratios of production workers to total employment for any manufacturing industry, far below the manufacturing average of 68.7 percent. Here are the data for 1967–84:

Year	*Wage and salary employees (thousands)*	*Production occupations (thousands)*	*Ratio of production occupations to total*
1967	145.1	68.2	.47
1970	193.8	75.0	.39
1975	210.4	76.9	.37
1977	239.1	95.8	.40
1979	318.9	131.4	.41
1982	403.3	153.4	.38
1984	460.9	174.3	.38

Projections

What follows is a number of different scenarios for output and employment growth of the computer industry over the 1984–95 period. (See table 4.) Nine scenarios were developed by combining three possible assumptions concerning implementation rates of technological advances along with the three levels of overall economic growth, described in the article entitled "Economic outlook to 1995: new assumptions and projections," which appeared in the November 1985 issue of the *Review*.

Output and employment projections reflecting the combination of the medium technological implementation rate with the varying economic growth levels were developed by the model described in the above article.[7] Additional output projections were made by pairing assumptions reflecting both a lesser and greater rate of technological development and implementation with each of the same three levels of economic growth and then analyzing the resulting expected impact on demand, production, and employment.[8]

Although there are nine alternative scenarios, the emphasis in this article is on the following three: low rate/low economic growth, medium rate/medium economic growth, high rate/high economic growth. These three scenarios will be referred to subsequently as the low, medium, and high scenarios.

A breakdown of the projected annual growth rates during the 1984–95 period for the components of demand is shown in table 5. The projections for the medium case were taken directly from the macro projections in the November article. The projected growth rates for the low and high scenarios were estimated through analysis of the possible interaction between the technological rates and the various rates of economic growth. This analysis by its nature was judgmental and subjective, particularly in that the assumed rates of technological use are broad in nature and are not specific to any given technology.

Before continuing, a caveat is in order. The constant dollar value of the computer manufacturing industry's output is difficult to measure because of the combination of unit price declines and increased unit capabilities, especially over the last several years. This problem arises because the fast pace of technological development, especially for the microcomputer, virtually redefines the product within a period of a few years. Consequently, it is difficult to make a unit price comparison as the product "unit" is not strictly comparable over the period of technological change.

In December, the Bureau of Economic Analysis released a new deflator for this industry. The deflator increases the historical real output of the computer manufacturing industry, compared with the real output as measured by the defla-

Table 3. Total employment for all of manufacturing and computer manufacturing, 1960–84, selected years

[Numbers in thousands]

Year	Total manufacturing	Computer manufacturing	Computer manufacturing as percent of total
1960	17,152	116	0.7
1965	18,400	148	.8
1970	19,064	228	1.2
1975	18,614	238	1.3
1976	19,305	239	1.2
1977	20,014	252	1.3

Table 4. Output and employment in computer manufacturing under alternate projections of economic growth and technological development, 1984–95

[1977 dollars in millions]

Rate of technological development	Economic projections			Compound annual rate of growth[1]		
	Low	Medium	High	Low	Medium	High
Output						
Low	$78,773	$92,915	$106,857	5.7	7.3	8.6
Medium	92,793	104,315	117,846	7.2	8.4	9.6
High	102,881	122,107	138,300	8.3	10.0	11.2
Employment						
Low	527,000	685,000	715,000	2.5	3.3	3.7
Medium	679,000	713,000	741,000	3.2	3.7	4.1
High	705,000	723,000	760,000	3.6	3.8	4.3

[1] In 1984, output was $43,021 million, and employment totaled 479,000 jobs.

NOTE: See text for discussion of problems of measuring constant dollar output. Employment covers wage and salary jobs.

tor used in this study. The Bureau of Labor Statistics has also undertaken an effort to improve measures of price changes among the range of computer products. Preliminary results of these studies indicate that the historical measure of real output on which the original projections were based is probably understated. Because this study presents alternatives to those projections, however, that output measure is used in the interest of continuity. The use of this historical output series, however, should not be construed as implying a final decision on the relative merits of alternative measures.

Technological factors. One of the most influential technological advances during the next 10 years is expected to be continued increases in computing power. This year, the first "micron" computer chips are expected to become available in the semiconductor marketplace. These chips have 4 times the storage capacity of the 256K RAM chips. Half-micron and quarter-micron computer chips with even greater storage capacity are widely predicted by the mid-1990's. Each successive generation of micron and sub-micron computer chips should spur the development of computers with increased computing power.[9]

This power should enable software designers to develop more complex programs for the personal computer. With continued advances in hardware and software, tasks that now require mini or mainframe computers can be expected to be accomplished in the future with the use of personal computers. Software also can be expected to continue to become easier to use. Additional computing power should facilitate greater use of artificial intelligence techniques in software designs, resulting in a variety of decisionmaking software that develop analytical conclusions based on user-defined parameters.

Both software and hardware are also expected to become increasingly targeted for specialty markets both in business and in the home. Doctors have a need for diagnostic and other medical software. Lawyers require specialized word-processing software. Other markets include computer-aided design and engineering, scientific research and development, and total factory automation. Small businesses also often have specialized tasks to perform that require different capabilities than the spreadsheet, word processing, and inventory and accounting software that is generally available. This is expected to change over the course of the next 10 years as software becomes more specialized for business purposes. In the home, as well, the computer should become more accepted as a useful appliance with an increased variety of specialized programs that focus on hobbies, educational interests, entertainment, and productivity in the household.[10]

The linking of microcomputers to each other and shared data bases also is an innovation that should stimulate investment demand for computers. Businesses want the ability to communicate among their mainframes, mini-, and microcomputers regardless of the manufacturer. Through 1985, computer equipment by different manufacturers was for the most part incompatible in such a network; however, it is expected that this problem will abate through the mid-1990's.

Telecommunications networks that provide electronic banking, brokerage, shopping, and data retrieval services should play a more influential role in the future growth of the computer industry. These networks offer convenient banking, brokerage, and shopping services. They also supply a necessary adjunct to microcomputers in providing access to data bases. Telecommunications networks undoubtedly will influence the personal computer market for homes and businesses as they expand their markets and services.

The optical laser disk as a medium for data storage is another development likely to contribute to the growth of the computer industry. The optical disk can store roughly a thousand times the amount of information that can be stored on a $5^1/_4$-inch floppy disk. This makes the disk an ideal medium for data storage as an accessory to the microcomputer, which has limited ability to store raw data. The dissemination of data bases on optical disks is already a reality in the form of encyclopedias.[11]

The development of more powerful microcomputers, the increased availability of more specialized and more powerful software and the advances in networking, telecommunications, and optical disk technology are all expected to provide the stimulus for additional growth in the computer industry through 1995. The extent that these expected advances contribute to the computer industry's growth is dependent upon the pace of adoption. Without specific references to any given technological development, the implementation rates presented in the projection scenarios are specified in terms of their effect on growth prospects for the industry.

Business investment and government spending. A moderate rate of technological development and implementation combined with a generally favorable economy is assumed to encourage both business investment and government spending in the medium scenario. Business investment in computer equipment is projected to grow annually at a rate of 8.3 percent. Federal Government spending is projected to grow 7.1 percent annually and State and local government spending, 6.5 percent.

In the low scenario, a low rate of technological development and implementation coupled with a generally sluggish economy is assumed to hamper both business investment and government spending. Consequently, business investment is projected to have a growth rate of 5.8 percent annually. The annual growth rate for Federal spending is a projected 4.7 percent and for State and local spending, 3.6 percent.

In the high scenario, with the combination of a rapid rate of technological development and implementation and a strong, investment-oriented economy, business investment is projected to grow at an annual rate of 10.9 percent. Government spending on computers at the Federal level is projected to rise at an annual rate of 9.3 percent and at the State and local level, 8.1 percent.

Personal consumption. The growth rates projected for personal consumption of the computer are high in all three alternatives. However, the overall impact on the industry in all cases is relatively low because personal consumption only represents from 6 to 8 percent of total industry production from a value viewpoint. Personal consumption is projected at about $8 billion, reflecting a 20.9-percent annual growth rate in the moderate alternative.

In the low scenario, a slow rate of development of a wide variety of specialized, user-friendly software is assumed to somewhat reduce consumer demand. As a result, the projected annual growth rate is 15.9 percent.

In the high scenario, the assumption of a strong economy coupled with the development of a wide variety of consumer software should have a stimulative effect on personal consumption. In this alternative, personal consumption is projected to grow at an annual rate of 24.3 percent.

Foreign trade. In the medium scenario, by 1995, the foreign exchange rate of the U.S. dollar is assumed to fall gradually to the level of 1980. The world economy is assumed to roughly parallel the generally favorable economy of the United States. These assumptions combined with a moderate rate of technological implementation are expected to stimulate exports for a projected 10.5-percent growth rate. Imports are projected to have an 11.8-percent annual growth rate, reflecting a strong domestic demand for computer products.

In the low scenario, the assumptions of a continuation of a strong U.S. dollar, a generally sluggish worldwide economy, as well as a slow rate of technological development and implementation are projected to hamper the growth in U.S. exports of computer products. Under these assumptions, U.S. computer firms should continue to find competition with foreign firms difficult and to move offshore to take advantage of lower labor and materials costs to remain competitive. Exports are projected to grow at an annual rate of 7.8 percent and imports at a rate of 9.5 percent.

Table 5. Alternative projections of output and consumption for computer manufacturing, 1984–95
[1977 dollars in millions]

Item	1977	1984	1995			Compound rate of growth			
						1977–84	1984–95		
			Low	Medium	High		Low	Medium	High
Industry output	$12,920	$43,021	$78,773	$104,315	$138,300	18.8	5.6	8.4	11.2
Intermediate use	3,176	9,809	18,429	23,701	31,320	17.5	5.9	8.3	11.1
Final users:									
Personal consumption	86	1,000	5,049	8,071	10,932	42.0	15.9	20.9	24.3
Business investment	6,159	26,529	49,311	63,590	82,437	23.2	5.8	8.3	10.9
Government									
Federal	1,078	5,564	9,255	11,628	14,773	26.4	4.7	7.1	9.3
State and local	121	626	926	1,246	1,477	26.5	3.6	6.5	8.1
Exports	3,215	10,525	23,962	31,472	41,071	18.5	7.8	10.5	13.2
Imports	−493	−8,392	−22,804	−28,969	−34,274	49.9	9.5	11.8	13.6

NOTE: Consumption totals exceed industry output slightly because a small percentage of total commodity output is produced as a secondary product by other industries. See text for discussion of problems of measuring constant dollar output for this industry.

Table 6. Alternative projections of employment for selected groups in computer manufacturing, 1984–95

[Numbers in thousands]

Occupation	1984		1995 low projections		1995 medium projections		1995 high projections	
	Employment	Percent	Employment	Percent	Employment	Percent	Employment	Percent
Total employment—SIC 3573-4	479.0	100.0	627.0	100.0	713.0	100.0	760.0	100.0
Managerial and management-related occupations	75.2	15.7	98.4	15.7	111.9	15.7	121.8	16.0
Engineers	59.4	12.4	94.0	15.0	101.2	14.2	129.2	17.0
Computer systems analysts	7.7	1.6	10.7	1.7	12.8	1.8	15.2	2.0
Technician occupations	57.5	12.0	92.8	14.8	95.5	13.4	121.6	16.0
Marketing and sales occupations	13.4	2.8	21.9	3.5	20.0	2.8	21.3	2.8
Administrative support occupations	87.7	18.3	102.8	16.4	117.6	16.5	125.4	16.5
Precision production occupations	27.8	5.8	34.5	5.5	40.6	5.7	41.6	5.5
Handworking occupations, including assemblers and fabricators	80.0	16.7	81.5	13.0	109.8	15.4	98.8	13.0

In the high scenario, the following conditions are assumed: the foreign exchange rate of the U.S. dollar declines to its 1980 level at a faster pace than in the medium scenario, the economic growth of the major trading partners of the United States roughly parallels the high growth of the U.S. economy, and there is a high rate of technological development and implementation. Under these assumptions, both foreign and domestic demand for computer equipment is expected to be high. The competitiveness of U.S. computer firms should also increase under these assumptions as the cost advantage of foreign labor and materials is reduced. Export growth is projected to increase at an annual rate of 13.2 percent, while imports are projected to have an annual growth rate of 13.6 percent.

Output. The output projections derived in the alternative demand scenarios previously discussed indicate that the computer manufacturing industry should remain vigorous. The projected growth rates for output during the 1984–95 period under the various scenarios range from 5.6 to 11.2 percent. However, as seen in table 4, the range is much narrower when focusing on all but the two most extreme scenarios. These rates, while slow by historical standards for this industry, would still exceed the rates of all but a handful of manufacturing industries even under the high growth scenario.[12] The output growth projected for this industry in all scenarios would approximately double the historical relationship of the computer industry to total manufacturing.

The medium scenario would result in a projected annual growth rate of 8.4 percent, a pace nearly 3 times faster than for all manufacturing industries.[13] The low scenario reflects an industry growing only half as fast as it did between 1960 and 1984. However, at a 5.6-percent annual growth rate this still would be 2.5 times the projected rate of growth for all of manufacturing.[14] The surging demand and increased competitiveness of U.S. computer manufacturers anticipated in the high scenario results in a projected annual growth rate of 11.2 percent.

Employment. The range of projected growth for employment, varying from 2.5 to 4.3 percent annually, is much narrower than the range for projected output growth. These projections assume continued improvements in productivity, accelerating in tandem with faster output growth. The anticipated gains in productivity are due to the assumption of some continued movement to offshore manufacturing sites, improvements in the production process utilizing automation and robotics, and the introduction of simpler but more powerful components.

Employment in the medium scenario is projected to reach 713,000 by 1995. Although this means the industry would grow at half its historical rate of employment growth, it would be expanding about 6 times faster than all manufacturing industries and would be one of the fastest-growing industries in the economy.[15]

The assumption of a moderate but continuous stream of technological advances described in this scenario can be expected to foster an increase in the number of engineers, technicians, and computer systems analysts. (See table 6.) As a group, they are projected to increase 4.8 percent annually and account for 29.4 percent of industry employment, 13 percent greater than their share in 1984. Production workers, however, are not anticipated to fare as well. Assumptions of continued gains in productivity would result in a projected decline in these occupations of 6 percent in terms of proportion of industry employment.

Reduced demand resulting from the conditions described in the low scenario would likely mean intense price-competition and tight profit margins. This in turn would sharply curtail employment, projected at 627,000 in 1995. New jobs would fall to 149,000. While indicating slow growth in the computer industry, these new jobs would represent almost 50 percent of the new manufacturing jobs projected in the low growth alternative.[16]

Production workers would be the most affected in this low scenario. Assuming the continued movement of the production process overseas, handworking occupations, including assemblers and fabricators, would see their share of industry employment decline by 22 percent. Precision production occupations would decrease by 10 percent. Reduced revenues for computer manufacturers assumed in this scenario would limit funds available for research and development, thereby lessening the rate at which new products enter the market. Under these conditions, engineers, technicians, and computer systems analysts would experience slow growth. They would, however, increase their share of industry employment as an offset to the decline of production workers.

Given the overall favorable conditions for domestic manufacturing coupled with accelerated implementation of technological advances assumed in the high scenario, employment in this industry is projected to reach 760,000 jobs in 1995. This would represent a vigorous 4.3-percent growth rate, nearly 17 percent faster than the rate projected in the medium scenario.

Despite the reduced movement to offshore manufacturing sites assumed in this scenario, the gap between the projected rates of growth for output and employment would continue to widen, assuming the achievement of higher productivity through technological advancements in product components and production methods. More funds are assumed to be devoted to R&D activities; therefore, engineers, technicians, and computer systems analysts are projected to more than double their 1984 employment and account for 35 percent of industry employment. Precision production and handworking occupations are projected to increase 30 percent in the high scenario. However, the share of industry employment represented by these occupations would decline nearly 18 percent as a result of assumed acceleration in productivity.

Summary and conclusions

The computer manufacturing industry has received a great deal of attention in the last 25 years. The advent of the microcomputer and the subsequent explosive expansion of output reinforced a perception that the industry's potential for growth was enormous. The slump of 1985, however, brought the realization that there were limits to this rapid growth. Given the assumptions used in this study, the computer manufacturing industry is seen as being strong and viable and likely to continue to grow, but at a less rapid rate than in the past. This is hardly surprising. The industry is maturing. Historically, the computer manufacturing industry has experienced periodic waves of rapid expansion; each wave precipitated by the introduction of a major technological advance, such as the mainframe, the minicomputer, and finally, the microcomputer. Now, after the microcomputer and without a new revolutionary computer on the horizon, the industry seems to be entering a period of stable growth that is characteristic of a maturing industry. Still, even without any new revolutionary breakthroughs anticipated through 1995, it is expected that the computer manufacturing industry will continue to be one of the strongest manufacturing industries. □

[7] Su, "Economic outlook to 1995." The following is a brief description of the three assumed economic growth levels:

High: Projected real GNP annual growth 1984–95 is 3.8 percent. Declining unemployment to 5.0 percent in 1995. High rate of business investment due to low capital costs and high profits. Declining foreign exchange rate of the U.S. dollar.

Medium: Projected real GNP annual growth 1984–95 is 2.9 percent. Declining unemployment to 6.0 percent in 1995. Strong rate of business investment. Declining foreign exchange rate of the U.S. dollar.

Low: Projected real GNP annual growth 1984–95 is 2.2 percent. Unemployment remains around 7.0 percent. Slow rate of business investment. Continuation of a strong U.S. dollar relative to foreign currencies.

In all three scenarios, the real economic growth of the Nation's major trading partners is assumed to more or less parallel that of the United States.

Work, poverty, and the working poor: a multifaceted problem

New study shows that most able-bodied heads of poor households demonstrate strong labor force attachment, but their employment tends to be intermittent, low-paying, or both

SHELDON DANZIGER AND PETER GOTTSCHALK

In 1984, the poverty rate for all households in the United States was slightly less than the rate for 1967 and at about the same as that in 1971.[1] About one-fourth of all heads of household whom we classified as "expected to work" had low weekly earnings. However, about 60 percent of these households escaped poverty.

This article describes changes from 1967 to 1984 in the economic status of households headed by persons who are expected to work. It compares the situations of households that are "poor" with those headed by "low earners." Excluded from the group expected to work are householders who are over age 65, the disabled, students, or women with a child under age 6.[2] Our results cast doubt on a common perception that most poor households are impoverished because their heads, though capable of doing so, do not work.[3]

A household is classified as poor if its cash income, of all types and from all household members, falls below the official poverty line for a household of its size. We define low earners as household heads with weekly earnings below $204 per week in 1984 dollars. Such persons could not earn the poverty-line annual income for a family of four if they worked 52 weeks a year.[4]

Households headed by low earners are not necessarily poor. Whether or not the household is poor depends on the household's own poverty line and its annual cash income. Similarly, poor households do not necessarily have heads with low weekly earnings.[5]

As the following tabulation shows, there were 93.5 million households in the United States in 1984. Of these, 65.33 million had a head whom we classify as expected to work. Among this group of households, 17.03 million had low weekly earnings, but not all of them were poor:

All households (millions)	93.50
Head expected to work	65.33
Low weekly earners	17.03
Household is poor	6.09
Household is not poor	10.94
Others (earned above $204/week)	48.30
Household is poor	.57
Household is not poor	47.73
Head not expected to work	28.17
Household is poor	7.50
Household is not poor	20.67

By having a smaller family or other sources of household income, 10.94 million households were able to escape poverty. The heads of almost all poor households in which the head was expected to work had low weekly earnings (6.09 out of 6.66 million), while very few households in which the head did not have low weekly earnings were poor (0.57 out of 48.30 million). Thus, about 10 percent (6.66

Sheldon Danziger is a professor of social work and director of the Institute for Research on Poverty, University of Wisconsin–Madison. Peter Gottschalk is a professor of economics, Bowdoin College, and research affiliate, Institute for Research on Poverty.

out of 65.33 million) of all households in which the head was expected to work were poor in 1984.

Recent trends

Table 1 shows changes in the incidence of household poverty and the composition of all households and all poor households, classified by the characteristics of the household head, for selected years from 1967 to 1984. The poverty rate for all households declined from 17.1 percent in 1967 to 13.1 percent in 1979 and then rose to 15.2 percent in 1984, a rate that is quite close to that of 1971.

The proportion of all household heads expected to work declined slightly from 71.3 percent in 1967 to 69.9 percent in 1984. Among poor households, the proportion expected to work increased from 37.1 to 47.0 percent over this period, primarily because of the rapid decline in the incidence of poverty among the elderly. By implication, at most only half of the poverty population could be *directly* affected by increases in the demand for labor, inducements to supply more labor, or requirements to work.

The data in table 1 show that among all poor household heads expected to work in 1984, roughly equal proportions either did not work at all during the year, worked between 1 and 47 weeks, or worked all year. This is in contrast to 1967, when more than half of those expected to work (20.0 out of 37.1 percent) worked all year. An important cause of the decline in year-round work was the doubling of the unemployment rate between 1967 and 1984.

Table 1. Percent distribution of all households and poor households by selected characteristics of household head, selected years, 1967–84

Characteristic	1967	1971	1979	1984
All households	100.0	100.0	100.0	100.0
Head not expected to work	28.7	29.4	30.3	30.1
Elderly	19.3	19.5	19.6	20.0
Women, child under 6	2.0	2.4	2.8	3.1
Student	2.2	2.2	2.4	2.5
Disabled	5.3	5.3	5.5	4.6
Head expected to work	71.3	70.6	69.7	69.9
Weeks worked:				
0	3.9	4.5	4.4	5.9
1 to 47	7.2	9.8	9.8	10.0
48 to 52	60.2	56.4	55.4	54.0
Poor households	100.0	100.0	100.0	100.0
Head not expected to work	62.9	62.5	61.5	53.0
Elderly	40.4	34.7	27.6	20.1
Women, child under 6	7.0	9.8	12.6	12.8
Student	5.5	6.5	7.7	7.7
Disabled	10.0	11.5	13.6	12.3
Head expected to work	37.1	37.5	38.5	47.0
Weeks worked:				
0	8.3	10.1	11.8	15.1
1 to 47	8.8	12.2	14.0	16.8
48 to 52	20.0	15.2	12.9	15.1
Household poverty rate	17.1	15.0	13.1	15.2
Unemployment rate	3.8	5.6	5.8	7.7

NOTE: Columns may not add to subtotals because of rounding. Data for all tables are authors' computations from March 1968, 1972, 1980, and 1985 Current Population Survey data tapes.

Incidence of low weekly earnings

Between 1967 and 1979, the incidence of household heads with low weekly earnings as a proportion of all household heads expected to work averaged 19.4 percent, but increased to 26.1 percent by 1984. In 1984, 21.1 percent of all such men and 44.9 percent of the women had low weekly earnings. Thus, a substantial proportion of household heads could not keep a family of four out of poverty even if they worked 52 weeks at their current weekly earnings.[6] The following tabulation shows the incidence of low weekly earnings among male and female household heads who could be expected to work:

	1967	*1971*	*1979*	*1984*
Low weekly earners:				
All households	19.4	19.1	19.7	26.1
Men	13.9	14.1	14.4	21.1
Women	53.4	47.8	42.4	44.9

There were major differences in the incidence of, and trend in, low weekly earnings among male and female household heads. The incidence among men was much lower than that for women in every year studied. However, the incidence increased for men and decreased for women.

These trends did not change when we redefined the low earnings population as those whose weekly wage was insufficient to keep a family of three out of poverty—that is, the cutoff was lowered from $204 to $159 in 1984 dollars. The incidence of low weekly earnings for all household heads increased from 15.2 to 20.0 percent between 1967 and 1984 under this definition.

Escaping from poverty

Because the earnings of household heads can be supplemented by other sources of income and because the poverty threshold depends on family size, our measure of low earnings does not necessarily mean that the household is poor. Most poor household heads who are expected to work had low weekly earnings (91.4 percent), but most heads with low weekly earnings escaped poverty (64.2 percent).

Table 2 shows the methods by which households headed by those with low earnings escaped poverty. We classify low-earning household heads who escape poverty into one of the eight mutually exclusive categories shown. The classification is hierarchical: any household head who fits more than one category is classified only in the one closest to the top of the table.

Escape from poverty because of small family size indicates that even though the head's weekly earnings times 52 weeks was below the poverty line for a family of four, actual annual earnings did exceed the poverty line for this house-

Table 2. Percent distribution of all low-earning households escaping poverty by source of escape, selected years, 1967–84

Source	1967	1971	1979	1984
Percentage of all low-earning households escaping poverty	60.0	63.3	67.0	64.2
Total sources of escape	100.0	100.0	100.0	100.0
1. Family size less than four persons	52.5	50.2	47.7	43.5
2. Earnings of members other than head	26.0	23.6	23.6	27.1
3. Private income other than earnings[1]	8.3	11.7	11.6	13.4
4. Public cash transfers[2]	8.9	10.1	13.4	11.6
Combinations of sources:				
5. 2 and 3	0.8	1.2	0.8	0.8
6. 2 and 4	1.7	1.4	1.2	1.5
7. 3 and 4	1.7	1.6	1.5	1.8
8. 2, 3, and 4	0.1	0.2	0.2	0.2

NOTE: Totals may not add to 100.0 because of rounding. These sources of escape are computed in a hierarchical, mutually exclusive fashion in the order shown in rows 1–8.

[1] Private income other than earnings includes self-employment income from farm and nonfarm businesses, interest, dividends, rents, royalties, income from estates or trusts, private pensions, alimony, child support, and any other source of money income which was regularly received.

[2] Cash transfers include benefits from Aid to Families with Dependent Children, Supplemental Security Income, General Assistance, unemployment compensation, workers' compensation, government employee pensions, veterans' pension and compensation, and Social Security and railroad retirement.

hold. In other words, this household had fewer than four members.

For each of the next three categories—earnings of other household members, other private income (which includes interest, dividends, rents, private pensions, and so forth), and public cash transfers—we use the following procedure. First, we compute the gap between the household's poverty line and the head's earnings. If the amount of income from the first of these sources exceeds this gap, the household was taken out of poverty by this source. If not, we compare the next source to the poverty gap. If no single source exceeds the gap, but some combination of sources does, the household is classified into the appropriate combination shown in rows 5 through 8. For example, consider a household of four persons, two parents and two children, with a poverty gap that is $2,000 after the head's earnings have been counted. If the wife earned more than $2,000 *and* the household received more than $2,000 in transfers, the household would be categorized as escaping from poverty because of the earnings of members other than the head (row 2). However, if the wife earned $1,999 instead, the household would be counted as escaping because of cash transfers (row 4). If both amounts were $1,999, then escape would be via the combination of other earnings and transfers (row 6).

In every year, at least 60 percent of households whose heads were low earners escaped poverty. The largest category of escape (row 1) indicates that the earnings of the head exceeded the household's poverty threshold, implying a household of fewer than four persons. The next most important source was the earnings of other household members. Other private income sources and cash transfers follow in roughly equal importance. However, the role played by cash transfers is small, owing in part to the hierarchical nature of our classification, but also to the unavailability of cash transfer programs for many of those expected to work and the relatively small average level of benefits for recipients.[7]

Characteristics of the poor, expected to work

Table 3 shows selected demographic and economic characteristics of poor households in which the head is expected to work. Although only about 10 percent of all households in which the head was expected to work were poor in 1984, they represented almost half of all poor households.

The top panel of table 3 further classifies poor households headed by persons expected to work by sex, race, Hispanic origin, and presence of children. In 1984, roughly half of these households (51.4 percent) consisted of single individuals or childless couples. Of the remaining 48.6 percent with children, 27.6 percent were white, 13.2 were nonwhite, and 7.8 percent were Hispanic. Thus, while a majority of poor households with children were white, nonwhites and Hispanics were overrepresented.

Between 1967 and 1984, households headed by women with children over age 6 increased from 13.4 to 17.7 percent of poor household heads who are expected to work. This trend toward the feminization of poverty was more pronounced among all poor households, as the percentage of such households headed by women with children under age 6 increased from 7.0 to 12.8 percent over the study period. (See table 1.)

The bottom panel of table 3 shows, for poor households in which there were children and a head expected to work, the proportion who received cash transfers, the weeks worked per year by the heads, the average amounts of household transfers, and the earnings of heads who worked, in constant 1984 dollars. Between 1967 and 1984, the share of those who received transfers increased from 17.1 to 38.2 percent for male-headed households, and from 48.9 to 61.5 percent for households headed by women. Most of the increase for men was attributed to the increased Social Security, disability, and unemployment insurance benefits; most, for women, to increased welfare receipts. The average transfer amount (in 1984 dollars) peaked at $3,336 for men and $5,425 for women in 1971. Between 1971 and 1984, the average benefit declined substantially for single mothers.

The fact that fewer than 40 percent of poor male household heads and only about 60 percent of all poor female household heads received transfers in 1984 indicates a substantial and growing gap in the safety net for many poor children.

There was a sharp decrease between 1967 and 1984 in the proportion of men who headed poor households and worked all year (from 71.8 to 45.6 percent) and a sharp increase in the proportion of those who did not work at all (from 7.8 to 17.0 percent). This undoubtedly reflects increased unemployment rates, but may also reflect increased participation in transfer programs.[8] For women, the percentage who did not work at all diminished somewhat over the period, and the proportion working full year declined considerably (from 32.6 to 21.4 percent). Nonetheless, nearly half of the men and about 20 percent of the women (with children over age 6) who headed poor households worked all year in 1984.

For male household heads who worked, earnings in constant dollars declined substantially over the analysis period, reflecting both the decline in weeks worked and the increased incidence of low weekly earnings. Nonetheless, in every year studied, earnings were much more important to these households than were transfers. For female household heads who worked, earnings in constant dollars increased somewhat over the period. However, because more female- than male-headed households received transfers and fewer had a working head, transfers were their most important income source.

Table 3. Selected characteristics of poor households headed by those expected to work, selected years, 1967–84

Characteristic	1967	1971	1979	1984
Demographic composition:				
Total	100.0	100.0	100.0	100.0
White, non-Hispanic:				
Men with children	29.5	22.9	18.5	19.5
Women with children over age 6	7.8	7.4	9.0	8.1
Nonwhite, non-Hispanic:				
Men with children	11.5	8.5	5.7	6.2
Women with children over age 6	5.6	6.4	7.7	7.0
Hispanic:				
Men with children	([1])	4.8	4.3	5.2
Women with children over age 6	([1])	1.3	2.4	2.6
Households without children	45.6	49.0	52.3	51.4
Transfer recipiency and earnings:				
Male head with children:				
Percent receiving cash transfers	17.1	20.4	32.3	38.2
Average household transfers[2]	$2,871	$3,336	$3,066	$3,260
Percent working 0 weeks	7.8	10.6	10.7	17.0
Percent working 48 weeks or more	71.8	69.3	52.7	45.6
Average earnings of head[3]	$6,650	$5,820	$4,860	$4,484
Female head with children over age 6:				
Percent receiving cash transfers	48.9	62.3	61.9	61.5
Average household transfers[2]	$4,529	$5,425	$4,637	$3,925
Percent working 0 weeks	55.7	63.6	50.6	50.3
Percent working 48 weeks or more	32.6	25.5	18.3	21.4
Average earnings of head[3]	$3,531	$3,699	$3,763	$3,818

[1] Data relating to 1967 are not available for Hispanics. Both white and nonwhite categories for that year include Hispanics.

[2] In constant 1984 dollars for recipients. Cash transfers include benefits from Aid to Families with Dependent Children, Supplemental Security Income, General Assistance, unemployment compensation, workers' compensation, government employee pensions, veterans' pension and compensation, and Social Security and railroad retirement.

[3] In constant 1984 dollars for heads with earnings.

Table 4. Federal direct tax bill for a family of four with poverty-line earnings, selected years, 1965–84[1]

Year	Poverty-line earnings	Personal income tax[2]	Social Security tax (employee's share)	Total Federal tax	Effective tax rate[3] (in percent)
1965	$ 3,223	$ 31.22	$116.83	$ 148.05	4.4
1969	3,743	104.02	179.66	283.68	7.6
1971	4,137	54.18	215.12	269.30	6.5
1973	4,540	33.60	265.59	299.19	6.6
1974[4]	5,038	3.32	294.72	298.04	5.9
1975	5,500	−250.00	321.75	71.75	1.3
1977	6,191	−180.90	362.17	181.27	2.9
1978	6,662	−133.80	403.05	269.25	4.0
1980	8,414	−54.00	515.78	461.78	5.5
1982	9,860	285.00	660.62	945.62	9.6
1984	10,609	366.00	710.80	1,076.80	10.1

[1] The family of four is hypothetical. We assume it consists of a married couple with two children not living on a farm; has only one earner per family; and that all its income is from wages and salaries.

[2] The data from 1975 to 1984 include the earned income tax credit. A negative entry represents a refund to the family.

[3] Defined as total Federal tax as a percentage of family income.

[4] The Tax Reduction Act of 1975 rebated $100 of 1974 personal income taxes to a family at this income level.

Federal taxes of the working poor

While some able-bodied heads of poor households receive transfers, the majority of them work and pay taxes. Table 4 shows the amount of taxes that a hypothetical family of four at the poverty line (a low weekly earner by our definition) would have paid in Federal income tax and Social Security tax if he or she had worked all year and had had no other source of income.

In 1984, this family would have paid $366 in personal income taxes and $711 in Social Security taxes, or 10.1 percent of household income. Not only is this tax burden high in an absolute sense, but it is also high in comparison with the taxes imposed on similar poor households in earlier years. Although Social Security taxes steadily increased between 1965 and 1984, they were offset by reductions in Federal income taxes during the 1970's. The result was a decline in effective tax rates from 4.4 percent in 1965 to a low of 1.3 percent in 1975. This stands in sharp contrast to the steady increase in the effective tax rate on working poor households after 1975. Thus, if taxes were subtracted from the earnings data, the increased incidence of low weekly earnings over the 1967–84 period would be even greater than that shown in the text tabulation (p. 18). Moreover, a family with earnings only and a family with earnings and welfare benefits at a given income below the poverty level will be counted as equally poor in the census data, but the family with earnings only will have a lower spendable income owing to taxation.

OUR RESULTS SHOW THAT:

- Poverty for all households in 1984 was somewhat below the rate for 1967 and at about the same level as it was in 1971. Large changes have occurred, however, in the labor market characteristics of the poor during the period.

- The majority of the heads of poor households are not expected to work because they are either over 65 years of age, disabled, students, or women with children under 6 years of age.
- About a quarter of all household heads who are expected to work have low weekly earnings. About 60 percent of their households nevertheless escape poverty.
- Among the remaining poor households with an able-bodied head, most have substantial labor market attachment. About half of all poor able-bodied mothers whose youngest child is over age 6 work at some point during the year, as compared with about 80 percent of men who head poor households with children.
- Despite this work effort, poor households remain in poverty because of low annual earnings, which reflect both low weekly earnings and less than full-year work. And most of these households would remain poor even if their heads worked a full year at their current weekly earnings rate. □

FOOTNOTES

ACKNOWLEDGMENT: The authors acknowledge the contribution of Christine Ross and George Slotsve who provided valuable research assistance, and Elizabeth Evanson, editorial assistance.

[1] A household consists of a family or an unrelated individual. This differs from the Census Bureau's definition of a household which "consists of all persons who occupy a housing unit." *Characteristics of Households and Persons Receiving Selected Noncash Benefits: 1984*, Series P-60, No. 150, p. 109. For example, if an unrelated individual resides in the same housing unit as a family of four, we would have two households and the Census would have one. Our definition is consistent with the assumption that the family and the unrelated person do not pool their incomes; the Census definition is consistent with income-pooling.

[2] While child care responsibilities may complicate labor market opportunities for single-parent households with a child over 6, we nevertheless classify such persons as expected to work because this is consistent with existing welfare policies.

[3] Throughout this paper, we use the official measure of poverty as defined by the Census Bureau. This measure is based on cash income and does not account for the receipt of in-kind benefits, such as medicare, medicaid, and food stamps. Inclusion of benefits would lower the extent of poverty in any year, but would not alter the trends in work effort and the incidence of low earnings discussed here.

Data for valuing in-kind benefits are available only for the years since 1979. All the data presented are based on computations by the authors from the computer tapes of the March 1968, 1972, 1980, and 1985 Current Population Surveys, conducted by the Bureau of the Census.

[4] In 1984, the poverty level for a family of four was $10,609. We define any household head with weekly earnings below $204 as a low earner, regardless of his or her own household size. The poverty line for every family size is fixed in real terms and varies over time only because of changes in the Consumer Price Index. The same is true for our low-earnings threshold.

[5] For example, a head of a household of four persons who earns $250 per week would not be counted as a low earner even if she or he worked only 10 weeks in the last year. If this were the household's only income for that year, the household would be poor. However, the householder would not be classified as a low earner because her or his household would escape poverty through full-year work. Also, consider the head of a two-person household who earns $150 per week for 50 weeks, or $7,500 per year. We classify this head as a low earner, but the household is not poor because the poverty line for a two-person household is $6,762.

[6] Note that if a head did not work at all during the year, we consider him or her as a low earner, along with those whose weekly earnings fell below our threshold.

[7] When we recompute the low earnings cutoff on the basis of a poverty line for a family of three, the importance of family size obviously decreases. Nonetheless, a family size of less than three persons is still the largest single source of escape for households whose heads have low weekly earnings.

[8] We have shown elsewhere that the increased transfers can account for, at most, small declines in work effort over this period. See Sheldon Danziger and Peter Gottschalk, "The Poverty of Losing Ground," *Challenge*, May-June 1985, pp. 32–38.

The declining middle class: a further analysis

The proportion of employment in higher paying occupations increased for all groups during 1973-82; but the earnings distribution of these occupations shifted to include more lower paying positions

PATRICK J. MCMAHON AND JOHN H. TSCHETTER

Some observers argue that jobs in the U.S. economy are shifting from middle paying to low and high paying. Some attribute the shift, or bipolarization, to declining employment in smokestack industries and growth of high tech industries, low paying occupations, and service-producing industries.[1] Others attribute the shift to the movement of the baby-boom generation into the labor market.[2] Robert Lawrence of The Brookings Institution found bipolarization occurring between 1969 and 1983, and cited the changing age distribution of the labor force as the most compelling explanation.

Other observers argue that, while the events used to explain the bipolarization might be occurring, occupational shifts are not responsible. Neal Rosenthal of the Bureau of Labor Statistics looked at median weekly earnings by occupation and found a slight shift away from the middle paying jobs between 1973 and 1982.[3] More importantly, however, he found a decline in the proportion of lower paying jobs, which does not support the notion of bipolarization.

In this article, we replicate Lawrence's and Rosenthal's studies to determine why their respective results differ. We extended Rosenthal's analysis of occupational employment to the 1973–85 period and to several broad population groups and found, as he did, that the changes in occupational structure—whether caused by changing technologies, changing industrial employment patterns, or other factors—almost always caused a *declining* proportion of employment in lower paying occupations. We extended Lawrence's analysis of earnings distributions to the 1973–85 period and found, as he did, an *increasing* proportion of lower paying jobs. Why do the results of the two analyses differ? Further analysis showed that within occupational earnings groups, the earnings distributions had shifted downward, that is, each group included more lower paying positions.

Several caveats to these discussions should be noted. Discussions of the declining proportion of middle-income earners can focus on changes in the earnings distribution of individuals or changes in the earnings distribution of families. Changes in the earnings distribution of individuals may be caused by changes in the occupational structure of the economy that reflect changes in industrial structure and technology. In addition, changes in the earnings distribution within each occupation and changes in relative earnings among occupations can affect the earnings distribution of individuals. Changes in the earnings distribution of families are affected not only by these same factors but also by changes in family structure. For example, increasing

numbers of dual-earner families can lead to an increase in the proportion of families with high earnings and increasing numbers of single-person households can lead to an increase in the proportion of families with low earnings.

Issues of the debate

Of the many issues on structural and technological change, the one that currently attracts considerable attention and concern is the changing employment patterns—the employment decline in large heavy manufacturing industries and in blue-collar occupations, and the employment increase in high technology manufacturing and service-producing industries and in white-collar and service occupations. For example, 43 percent of the full-time wage and salary workers were employed in blue-collar and farm occupations in 1973, compared with only 35 percent in 1982.

Apprehension about these changes is widespread. In many countries, rising unemployment is considered the most striking social—perhaps even political—aspect of this structural change. Joyanna Moy has shown that the U.S. economy has proved to be more dynamic than most others, and so the alarm is less about a lack of jobs than about the growing proportion of "wrong types" of jobs.[4] The focus of the debate on structural change in the United States has been on the apparent loss of middle earnings jobs, which some argue have been replaced by both low and high earnings jobs.

The debate has become more complicated because additional explanations of the apparent bipolarization have been offered and bipolarization is thought to be affecting different population groups unequally. According to Lawrence, men are believed to have borne the brunt of bipolarization; women have not even experienced bipolarization.[5] Further, Lawrence says the entry of the baby-boom generation into the labor market and the resulting changes in the age distribution of the work force provide a more powerful explanation of bipolarization.

One major problem in this debate is the type of evidence offered. Some put forth anecdotal evidence. Others offer "hard" evidence, but for only a few industries or occupations—for example, the rapid growth of a few very low paying occupations and a few very high paying occupations in the service sector combined with the decline of a few middle paying occupations in the goods-producing sector. However, the evidence usually becomes less compelling when a broader focus is taken.[6] A few offer systematic or comprehensive data; these observers, however, cannot agree on who comprises the middle class over time. Some use occupations to define the middle class; others use earnings. In this analysis, we use one data base for both the occupational and earnings approaches, and then reconcile the conflicting findings.

Rosenthal's occupational approach

Like Rosenthal, we analyzed the declining middle-class thesis using data from the Current Population Survey on usual weekly earnings and on employment of full-time wage and salary workers by detailed occupation. The analysis identifies the effect of changes in occupational structure on the distribution of full-time workers among three earnings groups: low, middle, and high. We revised Rosenthal's original analysis to ensure a consistent data base for our analysis.[7] Because of substantial changes in occupational definitions introduced in 1983, shifts between 1982 (and earlier years) and 1985 cannot be measured.

To test the effect of changes in occupational structure on the distribution of workers into low, middle, and high earnings groups between the beginning and ending years, we (1) arrayed the detailed occupations in the ending year by usual weekly earnings and arranged them into thirds (bottom, middle, or top), with each third containing the same number of occupations; (2) summed the number of workers in the occupations in each third and calculated a percent distribution of the employment; and (3) arrayed employment in the beginning year for each occupation in the same order as in the ending year, and calculated the beginning-year percent distribution for each third. Consequently, an occupation was in the same third in the beginning year as it was in the ending year. Rosenthal analyzed 416 detailed occupations for 1973 and 1982; we analyzed 504 occupations for 1983 and 1985. The 1982, 1983, and 1985 data are annual averages; the 1973 data relate only to May.

All full-time workers. If bipolarization were occurring, the proportion of total employment in the middle third would decline between 1973 and 1982, and the bottom and top thirds would show an increase. The following tabulation shows the distribution of employment of full-time wage and salary workers in 1973 and 1982 by usual median weekly earnings in 1982, based on the occupational approach:

	Usual weekly earnings	*Percent distribution of employment*	
		1973	*1982*
Top third	$382 to $773	25.2	29.0
Middle third	264 to 382	34.2	32.5
Bottom third	71 to 264	40.6	38.5

The share of employment in the top third increased appreciably, the bottom share decreased, and the middle decreased, but less than the bottom third. Based on the declining proportion of employment in the bottom third, we agree with Rosenthal's conclusion that changes in occupational structure alone from 1973 to 1982, whether caused by technological change, the shift from goods- to service-producing industries, or other factors, do not support the notion of bipolarization.

The following tabulation shows our findings on the distribution of employment in 1983 and in 1985 by usual median weekly earnings in 1985, based on the occupational approach:

	Usual weekly earnings	*Percent distribution of employment*	
		1983	*1985*
Top third	$439 to $931	29.5	29.7
Middle third	301 to 439	33.6	34.1
Bottom third	100 to 301	37.0	36.3

The top and middle thirds increased, and the bottom third decreased. The changes in occupational structure since 1983 also are *contrary* to the bipolarization thesis.

Population groups. Have blacks, whites, men, women, youth, and adults all benefited from these occupational trends which have caused a declining proportion of lower paying occupations? To answer this question, we need to identify the changes in occupational structure of full-time workers in the three earnings groups separately for each of the six population groups. To do this, we (1) summed separately by population group the number of workers in each occupation for 1973 and 1982 according to Rosenthal's 1982 rankings for total employment by occupation, and (2) calculated the percent distribution of employment by usual weekly earnings class for each population group. The occupational structure varies considerably by population group and the respective structures are changing. More than half of the youth, women, and blacks who worked full time were in low paying occupations in 1982. (See table 1.) Nearly 40 percent of the men who worked full time were in high paying occupations, compared with only 14 percent of their female counterparts.

Table 1. Employment distribution for selected groups by earnings, based on the occupational approach, 1973 and 1982
[In percent]

	1973	1982
Youth, 16–24 years:		
Top third	11.4	14.5
Middle third	32.3	29.2
Bottom third	56.3	56.3
Adults, 25 years and older:		
Top third	28.6	32.0
Middle third	34.6	33.2
Bottom third	36.8	34.7
Men:		
Top third	34.9	39.0
Middle third	39.3	36.4
Bottom third	25.8	24.6
Women:		
Top third	7.5	13.9
Middle third	24.9	26.7
Bottom third	67.6	59.4
Whites:		
Top third	26.8	30.6
Middle third	34.6	33.0
Bottom third	38.6	36.4
Blacks:		
Top third	10.6	15.3
Middle third	31.2	29.9
Bottom third	58.2	54.8

For each group, the share of employment in the top third increased several percentage points between 1973 and 1982. However, only for women did the share of employment increase in the middle third. Men accounted for the largest decline in the share of middle paying occupations. Only younger workers did not experience a decline in the share of employment in the bottom third. Despite the varying patterns among the groups, the shifts in occupational structure of full-time workers do not support the notion of bipolarization, where employment in both the lower paying and higher paying occupations grows as a percent of total employment, while employment in middle paying occupations declines.

Lawrence's earnings approach

In Lawrence's analysis of the declining middle-class thesis, he distributed full-time workers into earnings classes that are a fixed or constant percentage of the median weekly earnings for all full-time workers. With this approach, Lawrence did find evidence of bipolarization between 1969 and 1983.[8] He said the most compelling explanation for the findings lies in demographic factors, not declining employment in smokestack industries or increasing employment in service industries. Further, he found the shifting age distribution to be the most important demographic factor.

The major difference between the occupational and earnings approaches is how the bottom, middle, and top earnings classes are tracked over time. In the occupational approach, one assumes that the "class" of occupations is stable over time. Thus, we only have to determine to which class an occupation belonged for a given year. In the earnings approach, one assumes that earnings levels which divide classes of workers are a fixed or constant percentage of the median weekly earnings for all full-time wage and salary workers. Thus, we only have to calculate the earnings groups for a given year.

We replicated elements of Lawrence's methodology for the 1973–85 period.[9] (Because of the changes in occupational definitions in 1983, it is not possible to calculate the 1969–83 shifts with the occupational approach.) Like Lawrence, we used the CPS data on usual weekly earnings of full-time wage and salary workers. To measure the changes in employment distribution by earnings groups between 1973, 1982, and 1985, we (1) arrayed the full-time workers in 1982 by usual weekly earnings and arranged them into thirds (bottom, middle, and top), with each third containing about the same number of workers; (2) assumed that the earnings level (or brackets) which divide the earnings groups are the same percentage of the median weekly earnings for full-time workers in both 1973 and 1985 as in 1982; and (3) arrayed the workers in the respective earnings classes in 1973 and in 1985 and calculated the distribution for each class. (The median usual weekly earnings of full-time workers used here are $152 for 1973, $300 for 1982, and $349 for 1985.)

If bipolarization were occurring, the proportion of total employment in the middle third would show a decline over time and the bottom and top thirds would show increases. The following tabulation shows the distribution of employment in 1973, 1982, and 1985 by usual weekly earnings in 1982, based on the earnings approach:

	Usual weekly earnings	*Percent distribution of employment*		
		1973	*1982*	*1985*
Top third	Over $385	33.3	33.5	32.6
Middle third	$239 to $385	34.8	33.5	31.7
Bottom third	Under $239	31.9	33.1	35.7

The shifts over the 1973 to 1982 period support the notion of bipolarization—declining employment share for the middle third, increasing shares for the bottom and top thirds. During the 1983–85 period, only the share for the bottom third increased; the shares for both the middle and top thirds decreased. While the shifts for the entire 1973–85 period do not support the bipolarization thesis because the top third decreased, they are of considerable concern because they show an increasing proportion of low paying jobs and a declining proportion of middle paying jobs.

Reconciling the findings

The most striking difference between the occupational and earnings approaches is the declining employment share in the bottom third with the occupational approach (1.9 percentage points), but an increasing share with the earnings approach (1.2 percentage points). To reconcile these conflicting findings, the two methods were combined. We (1) calculated for each detailed occupation the employment distribution by usual weekly earnings class in both 1973 and 1982, where the earnings class is defined by the earnings approach; (2) aggregated the individual occupations according to their rankings in the occupational approach; and (3) calculated the percentage distribution with the low, middle, and high paying occupations by earnings class.

As shown in the following tabulation, there has been a change in the earnings distribution of occupations, a downward shift:

Occupational approach	*Earnings approach*		
1973	*Top*	*Middle*	*Bottom*
All full-time workers	33.3	34.8	31.9
Top third	68.1	25.4	6.5
Middle third	35.9	43.3	20.7
Bottom third	9.6	33.4	57.0
1982			
All full-time workers	33.5	33.5	33.1
Top third	63.8	27.2	9.0
Middle third	34.5	42.1	23.4
Bottom third	9.7	30.9	59.4

Within those occupations ranked in the top third, the proportion of wage and salary workers who would fall in the top earnings category declined over the 1973–82 period, while the proportion of workers in the middle and bottom earnings categories increased. And different patterns hold for each group of occupations. Within those occupations ranked in the middle third, the proportion of wage and salary workers in the top and middle earnings category declined over the 1973–82 period, while the proportion in the bottom earnings categories increased. Within those occupations ranked in the bottom third, the proportion of wage and salary workers who would fall in the middle earnings category declined, while the proportion in the top and bottom earnings categories increased.

There are many possible explanations for the changes in earnings distribution within the occupational groupings. Unfortunately, sufficient data are not available to evaluate the impact of individual factors, and it is likely that there would be interactions among the factors. The following discussion highlights possible explanations for the changes.

The downward shift might be an experience or tenure effect. Three elements are required to make this point. First, earnings within an occupation are positively related both to occupational tenure (length of time in the occupation) and to job tenure (length of time with the current employer).[10] Second, women, on average, have less experience or tenure then men within individual occupations; younger workers have less experience than older workers. Third, a greater percentage of the full-time workers in 1982, compared with 1973, were under age 35, and a greater percentage were women. Thus, the younger, more female 1982 work force, compared with the 1973 work force, implies less experience or tenure within individual occupations and, thus, smaller earnings. For example, there was a dramatic increase in the percentage of high paying jobs which were held by women over the period, from 11 percent in 1973 to 19 percent in 1982. Such a large change suggests a significantly different tenure mix in the high paying occupations. Similar but less dramatic changes occurred for the middle and low paying occupations.

The explanation for the changing earnings distributions within the occupational groupings might be a cohort effect. According to Richard Freeman, Robert Lawrence, and others, the baby-boom generation is so large that the earnings within the generation are depressed when compared with other generations.[11] If their thesis is valid, then the changing mix of generations within the work force that began in the early 1970's would have had a negative effect on the earnings distributions. Lawrence found this to be the most compelling explanation.

The changes in earnings distributions within occupations might be an industry effect. Of the 416 occupations in the 1982 analysis, 274 had full-time workers in both the goods- and service-producing industries. The median usual weekly earnings were higher in goods-producing industries for 181 of those occupations. The absolute difference in earnings across the 274 occupations was $78 (the difference without regard to sign). Most earnings studies only compare the median weekly earnings or hourly earnings of industries, not the occupational earnings by industry.

The changes in employment are sensitive to the economy's movement through the various stages of a business cycle. The 1973–82 shifts occurred as the economy moved from a business cycle peak to a trough. The entry-level earnings for most occupations may have been depressed when compared with 1973 because 1982 was the low point of the business cycle.

Finally, in response to innovations, international competition, cost consciousness, or other demand-oriented factors, companies might have made some significant changes in organizational structure. For example, they may have reduced the levels of management; substituted entry and mid-level personnel for senior personnel; and contracted for goods and services, rather than providing similiar services with inhouse staff. At some point, such changes would affect the earnings distributions of individual occupations.

Part-time workers

At some point, the potential substitution of part-time workers for full-time workers must be considered when examining trends in the number of middle-class workers. (Rosenthal's findings did not change when part-time workers were included in his original analysis.) Substitution could consist of long-term, secular trends (such as businesses expanding working hours or employers accommodating workers seeking part-time work) or it could be a cyclical phenomenon, for example, decreasing work hours during a recession as demand slackens.

The percentage of all employed persons working part time is indicative of these phenomena. The following tabulation shows the proportion of workers on full-and part-time schedules, selected years, 1973–85:

	1973	*1982*	*1983*	*1985*
Full-time	83.0	79.5	79.7	81.0
Part-time for economic reasons	3.0	6.2	6.2	5.2
Voluntary part-time	14.0	14.3	14.1	13.8

The percentage of employed persons voluntarily working part time has changed little over the last 12 years; the percentage working part time for economic reasons has fluctuated with the movement of the economy through business cycles.

To estimate the impact of part-time employment on detailed occupations by usual weekly earnings class, we (1) arrayed the detailed occupations in 1985 by the usual weekly earnings of full-time workers and arranged them into thirds; (2) summed total workers, full-time workers, and part-time workers in each third and calculated the respective distributions of employment; and (3) arrayed the total, full-time, and part-time workers for each occupation in the same order as in 1985, and calculated the respective 1983 distributions. (The data do not permit distinguishing between types of part-time workers.) The following tabulation shows the distribution of total, full-time, and part-time employment in 1983 and 1985, based on occupational earnings:

	Total		*Full-time*		*Part-time*	
	1983	*1985*	*1983*	*1985*	*1983*	*1985*
Top third	25.2	25.6	29.5	29.7	7.5	7.4
Middle third	30.2	31.0	33.6	34.1	16.5	17.3
Bottom third	44.6	43.5	37.0	36.3	76.1	75.3

The share of middle earners increased slightly for each distribution. Part-time workers were certainly concentrated in occupations ranked in the bottom third; but the share of part-time workers in the bottom third declined over the period.

We can conclude from this calculation that the patterns of occupational shifts whether measured in terms of all workers, full-time workers, or part-time workers are comparable. Therefore, the substitution of part-time workers for full-time workers is not a valid explanation for the declining proportion of workers in low paying occupations.

TWO STUDIES OF THE DECLINING MIDDLE-INCOME thesis were analyzed to put them on equal footing. The original studies were based on different periods as well as different approaches. Our reconcilation showed that there was a significant change in the earnings distribution in all three occupational earnings groups—top, middle, and bottom—between 1973 and 1982.

One should be cautious in applying these findings to the future because we were not able to identify the cause of the changing earnings distributions. And the trends for some of the possible variables offered as explanations will be considerably different during the next decade, compared with the past decade. For example, according to BLS' labor force projections, the 1995 labor force will be older and more experienced than the current labor force.[12] Thus, if tenure and experience were the proper explanation for the 1973–82 earnings shifts within occupations, then the shifts might reverse during the next decade. However, the recent trends for the cohort effect—the presence of the baby-boom generation in the labor market—will continue through the next decade. □

Steinberg, *Deindustrialization and the Two Tier Society* (AFL-CIO, Industrial Union Department, 1985); and M. Harrington and M. Levinson, "The Perils of a Dual Economy—A Growing Trend in the American Occupational Structure," *Dissent*, Fall 1985, pp. 417–26.

The intellectual stimulus to the debate initially came from B. Bluestone and B. Harrison, *The Deindustrialization of America* (New York, Basic Books, Inc., 1982). Proponents of the disappearing middle class have since construed the decline in employment in the smokestack and goods-producing industries along with a simultaneous growth in the high tech and service-producing industries as synonymous with a bipolarization of the earnings structure. They often point to the differential growth rates of employment in a small number of occupations identified with these industries. The argument is loose and no evidence to support a bipolarization in the earnings distribution arising from shifts in the occupational structure has ever been published.

[5] Lawrence, "Sectoral Shifts."

[6] Rosenthal, "The shrinking middle class." Rosenthal examined the linkages between several phenomena—declining employment in smokestack industries, rapid growth of service industries, and so forth—on earnings distribution. He found that, in each instance, when comprehensive data were reviewed, the impact of each phenomenon on the earnings distribution was either negligible or nonexistent.

[7] Rosenthal's data were recalculated for two reasons. First, BLS periodically revises its procedures for estimating median weekly earnings. The median weekly earnings in this article for the detailed occupations are estimated based on $10 centered intervals. Data for the median weekly earnings of full-time workers are based on the "true" median of the sample. The medians are revised because earnings tend to be clustered at certain points, usually around $50 intervals. This clustering can affect the estimated changes in median earnings. Second, the May 1973 data used were revised to include only those responding to the usual weekly earnings question. Rosenthal included all respondents in his calculation. This second revision was necessary for subsequent analysis in this article. The two revisions had a very slight impact, certainly not a qualitative impact.

[8] Lawrence, "Sectoral Shifts."

[9] Lawrence's calculations involved four steps: he (1) centered the earnings of the middle class around the median usual earnings of men ($379) as of 1983; (2) calculated the 1983 employment distribution of full-time workers by usual weekly earnings class; (3) centered the middle class for 1969 around the median usual weekly earnings of men in 1969 ($142) and assumed the earnings brackets were the same percentage of male medium weekly earnings in both 1969 and 1983; and (4) calculated the 1969 employment distribution using the 1969 earnings class. The usual weekly earnings for Lawrence's middle class were $250 to $499 in 1983, and $94 to $187 in 1969. Between 1969 and 1983, the change in male weekly earnings and change in the Consumer Price Index were nearly equal.

Because of his approach, Lawrence might have overstated the decline in the proportion of workers in the bottom earnings group. First, he centered his middle class about the median weekly earnings of men in both 1969 and 1983. He might have centered his middle class about the median weekly earnings for all full-time workers, as we have done in our analysis. Thus, his middle class is not divided evenly between workers with earnings above and below the median for all full-time workers. Further, he uses the male median weekly earnings over time to establish the earnings levels which divide the classes. We used total median weekly earnings. If he had used the median weekly earnings for all full-time workers, the earnings levels which divided the middle and lower earnings groups would have been $10 higher in 1983. With his approach (male earnings), the proportion of workers in the bottom third declined 3 percentage points; with our approach (full-time workers' earnings), the proportion of workers would have increased slightly. Thus, his results would have been qualitatively different with a different median.

The earnings approach (and the occupational approach) was not sensitive to the boundaries chosen to divide the classes of workers or to the number of classes considered. The middle might have been represented by 50 percent of the work force; shifts between 3, 4, or 10 classes might have been considered.

[10] The literature on earnings is extensive, but usually focuses on earnings differences by sex or race. Recent research by the BLS on earnings differences between men and women was published in a series of articles in the June 1984 *Monthly Labor Review*. In one of the articles, Earl Mellor showed that women receive less pay than men in almost all occupational groups which employ both men and women. For most jobs, full-time usual weekly earnings of women in 1982 were 60 to 80 percent of those of men. Readers should be wary of interpreting these differences as evidence of discrimination for many of the reasons discussed by Mellor.

Research Summaries

Weekly earnings in 1985: a look at more than 200 occupations

EARL F. MELLOR

This summary presents 1985 annual average data on the median weekly earnings of workers in more than 200 occupational categories. The data are obtained through the Current Population Survey (CPS), a nationwide sample survey conducted for the Bureau of Labor Statistics by the Bureau of the Census. Covered are wage and salary workers (excluding the incorporated self-employed) who usually work full time (35 hours or more per week).

First published in 1982, this annual series is also available in unpublished form back to 1979.[1] When making year-to-year comparisons, several caveats must be taken into account. One concerns the occupational classification system. The present system, developed for the 1980 census, was introduced into the CPS in 1983.[2] Because the new classification system is vastly different from the previous one, 1983–85 data are not comparable with those available for 1979–82.

Another caveat relates to the procedure currently used to estimate median weekly earnings. Prior to 1983, medians were estimated using the linear interpolation of $50- to $100-wide intervals. Medians for 1983 and 1984 were initially estimated via the interpolation of $10-wide uncentered intervals. This change was introduced to reduce a systematic upward bias resulting from the use of wider uncentered intervals for earnings data, which are subject to a high incidence of rounding by CPS respondents. In 1985, the procedure was changed back to $50-wide intervals, but these were centered on multiples of $50. This newer procedure lessens the sometimes erratic movements in medians caused by having a large number of narrow intervals. The data for 1983 and 1984 have been revised using the new procedure and are available from BLS on request, but earlier medians are still based on the old (pre-1983) procedures.

As in previous years, the data in table 1 are limited to those occupations with at least 50,000 employed wage and salary workers who usually work full time. The table presents median weekly earnings in 230 non-overlapping occupational groupings, and male-female comparisons are shown for 85 such groupings.

Obviously, within each of the occupations shown, there is likely to be a wide range of money earned among individual workers. This is because each occupational group still has many different jobs for which data are not tallied separately. Each occupation has specialties with differences in skill levels, market demand for the jobs, and other variables. Also, workers in each specialty may have different duties, responsibilities, work schedules, and job tenure.

In addition, caution must be used in interpreting differences between groups, particularly when either the number of workers in a job category is small or there are comparatively small differences between earnings medians. This is because the estimates are based on a sample and, accordingly, are subject to sampling errors.

Earl F. Mellor is an economist in the Division of Employment and Unemployment Analysis, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

FOOTNOTES

[1] Data for 1981 appear in "1981 Weekly Earnings of Men and Women Compared in 100 Occupations" (News Release, March 7, 1982) and in Nancy F. Rytina, "Earnings of men and women: a look at specific occupations," *Monthly Labor Review*, April 1982, pp. 25–31. For 1982 data, see Earl F. Mellor, "Investigating the differences in weekly earnings of women and men," *Monthly Labor Review*, June 1984, pp. 17–28. For 1983 data, see Earl F. Mellor, "Weekly earnings in 1983: a look at more than 200 occupations," *Monthly Labor Review*, January 1985, pp. 54–59; however, these data were subsequently revised. The revised data for 1983 and 1984 are available by either writing to the Bureau of Labor Statistics or calling (202) 523–1371. For more information on the nationwide sample survey from which these earnings data were obtained, see Earl F. Mellor, *Technical Description of the Quarterly Data on Weekly Earnings from the Current Population Survey*, Bulletin 2113 (Bureau of Labor Statistics, 1982), or Earl F. Mellor, "Earnings statistics from the Current Population Survey," *BLS Measures of Compensation*, Bulletin 2239 (Bureau of Labor Statistics, 1986).

[2] The system evolved from the Standard Occupational Classification System which was adopted in 1977 and revised in 1980. See *Standard Occupational Classification Manual* (U.S. Department of Commerce, Office of Federal Statistical Policy and Standards, 1980). The relationship between the 1980 census system and the classification system is shown in *Census of Population: 1980, Classified Index of Industries and Occupations*, Report PHC80-R4, final ed. (U.S. Bureau of the Census, 1983).

[3] For information on the standard error and other limitations of the data, see *Technical Description of the Quarterly Data on Weekly Earnings from the Current Population Survey*, Bulletin 2113 (Bureau of Labor Statistics, 1982). For information on other data series on earnings from the Current Population Survey and other BLS surveys, see *BLS Measures of Compensation*.

Table 1. Median weekly earnings of wage and salary workers who usually work full time in occupations employing 50,000 or more, by sex, 1985 annual averages

[Numbers in thousands]

Occupation	Both sexes		Men		Women		Ratio female/male earnings times 100	Percent female workers
	Employed	Weekly earnings	Employed	Weekly earnings	Employed	Weekly earnings		
Total	77,002	$343	45,589	$406	31,414	$277	68.2	40.8
Managerial and professional specialty occupations	19,361	488	11,078	583	8,302	399	68.4	42.8
Executive, administrative, and managerial occupations	9,328	497	5,836	593	3,492	383	64.6	37.4

Estimating the number of undocumented aliens

JEFFREY S. PASSEL

Prior to January 1986, the Census Bureau's postcensal population estimates included no allowance for undocumented immigration.[1] Even though there was widespread recognition of the phenomenon, the only estimates of the magnitude of undocumented immigration, particularly of the annual flow, were based on little more than speculation. Research conducted at the Census Bureau over the last several years[2] has shown that undocumented aliens appearing in censuses and surveys can provide a basis for measuring at least a portion of undocumented migration to the United States.

Estimates of the number of undocumented aliens included in the 1980 census were derived by comparing two different sets of estimates:[3] (1) estimates of the total number of aliens included in the 1980 census: and (2) estimates of the number of aliens residing legally in the United States at the census date, derived primarily from the Immigration and Naturalization Service (INS) data. The difference between the two estimates is assumed to be the result of undocumented aliens being included in the 1980 census.

Both sets of data used to derive the estimates—1980 census data on the foreign-born population and 1980 alien registration data from INS—required a number of corrections and modifications to account for known deficiencies. The census data were corrected for nonreporting of country of birth, misreporting of citizenship status, and misreporting of nativity. The INS data were corrected for underregistration and nonreporting of country of birth.

A comparison of the independently derived estimates of the legally resident population on April 1, 1980, with the 1980 census count of aliens shows that 2,057,000 undocumented aliens were included in the 1980 census. Of these, 1,131,000, or 55 percent, were born in Mexico. No single country other than Mexico accounts for as much as 5 percent of the total. An estimated 1,517,000, or 75 percent, of the undocumented immigrants counted in the census entered the United States during the 1970's, with 946,000 (or 46 percent) entering during the 5 years prior to the 1980 census.

A supplement to the April 1983 Current Population Survey (CPS) provided data on country of birth, year of immigration, and citizenship that were used to estimate growth of the undocumented alien population since the 1980 census.[4] An estimate of the foreign-born population residing legally in the country in 1983 was first developed by carrying forward the estimate for 1980 by adding legal immigration and by subtracting mortality and emigration during the intervening period. The difference between the estimated legally resident foreign-born population and the total foreign-born population in the April 1983 CPS gives the number of undocumented aliens in 1983. Because the CPS sample is smaller than the census and because of other inherent limitations, the 1983 estimate of undocumented aliens is less precise than the estimate for 1980. In spite of such limitations, the research shows that the undocumented alien population grew by between 100,000 and 300,000 per year between 1980 and 1983.

On the basis of these studies, the Census Bureau's postcensal estimates have been revised to allow for net annual undocumented immigration of 200,000 for every year since 1980. Approximately 70 percent of the undocumented immigrants are Hispanic. The items needed to develop further estimates of undocumented aliens were included in a supplement to the June 1986 CPS. On the basis of these data, the Census Bureau plans to update the estimates of growth in the undocumented alien population and, if necessary, revise the estimates of net annual undocumented immigration. Until the research based on the June 1986 CPS supplement is completed, the figure of 200,000 will continue to be used for net annual undocumented immigration. ☐

Jeffrey S. Passel is chief of the Population Analysis Staff, Population Division, Bureau of the Census. This report is drawn from "Changes in the Estimation Procedure in the Current Population Survey Beginning January 1986," *Employment and Earnings*, February 1986.

———*FOOTNOTES*———

[1] Various terms have been used to refer to this group of noncitizens present in the United States who entered illegally or who violated their conditions of entry. In addition to undocumented immigrants, some examples include illegal aliens, undocumented workers, nonlegal residents, and illegal entrants.

[2] Robert Warren and Jeffrey S. Passel, "A Count of the Uncountable: Estimates of Undocumented Aliens Counted in the 1980 United States Census, forthcoming in *Demography*"; Jeffrey S. Passel and Karen A. Woodrow, "Geographic Distribution of Undocumented Immigrants: Estimates of Undocumented Aliens Counted in the 1980 Census by State," *International Migration Review* 18, Fall 1984, pp. 642–71; Passel and Woodrow, "Growth of the Undocumented Alien Population in the United States, 1979–1983, as Measured by the Current Population Survey and the Decennial Census," paper presented at the 1985 annual meeting of the Population Association of America, Boston, MA, March 1985.

[3] Details of the estimation procedure can be found in "A Count of the Uncountable." It must be stressed that the research regarding undocumented aliens included in the 1980 census did not compromise the confidentiality of U.S. census data that is required by law. No attempt was made to determine the legal status of individual aliens. The estimates were developed by comparing statistical aggregates, not by determining the legal status of individuals.

[4] The estimation procedures and underlying assumptions are described in "Growth of the Undocumented Alien Population."

Major Agreements Expiring Next Month

This list of selected collective bargaining agreements expiring in October is based on information collected by the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more. Private industry is arranged in order of Standard Industrial Classification.

Industry or activity	Employer and location	Labor organization[1]	Number of workers
Private			
Construction	Southeastern States Boilermaker Employers (Interstate)	Boilermakers	7,000
	Independent Contractors (Southern and Western Florida)	Operating Engineers	1,200
Food products	Keebler Co. (Interstate)	Bakery, Confectionery and Tobacco Workers	3,550
	Hershey Foods Corp. (Pennsylvania)	Bakery, Confectionery and Tobacco Workers	2,800
Paper	James River Corp., Dixie Northern Division (Naheola, AL)	Paperworkers	1,300
Stone, clay, and glass products	Owens-Illinois, Inc. (Vineland, NJ)	Flint Glass Workers	1,600
	Anchor Hocking Corp. (Lancaster, OH)	Flint Glass Workers	4,000
	Owens-Illinois, Inc. (Toledo, OH)	Flint Glass Workers	1,200
Primary metals	Allegheny Ludlum Industries, Inc. (Interstate)	Steelworkers	5,400
	Lukens Steel Co. (Coatesville, PA)	Steelworkers	1,400
	Lone Star Steel Co. (Texas)	Steelworkers	2,300
	Laclede Steel Co. (Alton, IL)	Steelworkers	2,000
	Cyclops Corp., Empire-Detroit Steel Division (Mansfield, OH)	Steelworkers	1,100
Fabricated metal products	Kohler Co. (Wisconsin)	Auto Workers	3,000
Machinery	Koppers Co., Inc., Metal Products Division (Baltimore, MD)	Machinists	1,350
	Outboard Marine Corp., Johnson Outboard Division (Waukegan, IL)	Marine and Machinists Association (Ind.)	1,700
Electrical products	Bendix Corp. (Sidney, NY)	Machinists	2,100
Transportation equipment	Boeing Co. (Interstate)	Machinists	26,000
	General Dynamics Corp., Quincy Shipbuilding Division (Quincy, MA)	Marine and Shipbuilding Workers	2,300
	Boeing Co., Boeing Vertol Division (Philadelphia, PA)	Auto Workers	2,400
	Lockheed-Georgia Co. (Interstate)	Machinists	10,000
	Lockheed Aircraft Corp., Lockheed-California Co. (California)	Machinists	10,000
	Lockheed Aircraft Corp., Missile & Space Division (California)	Machinists	5,000
	McDonnell Douglas Corp. (California)	Machinists	3,500
	McDonnell Douglas Corp. (California)	Auto Workers	4,800
	McDonnell Douglas Corp. (Arkansas and Oklahoma)	Auto Workers	1,800
Transit	Greyhound Lines, Inc. (Interstate)	Transit Union	12,700
Air transportation	United Airlines, ground service (Interstate)	Machinists	15,500
Retail trade	The Great Atlantic and Pacific Tea Co. (New York)	Food and Commercial Workers	8,800
	Jewel Food Stores (Illinois and Indiana)	Retail, Wholesale and Department Store	18,000
	Kroger Co. (Cincinnati, OH)	Food and Commercial Workers	3,300
	Giant Eagle Food Stores (Pittsburgh, PA)	Food and Commercial Workers	3,500
	Kohl's Food Stores (Wisconsin)	Food and Commercial Workers	3,000
Restaurants	East Bay Restaurant Association (San Francisco, CA)	Hotel Employees and Restaurant Employees	2,000
	On-Sale Liquor Store Dealers (Minneapolis, MN)	Hotel Employees and Restaurant Employees	1,500
Hospitals	Kaiser Permanente (Northern California)	Service Employees	6,400
Public			
Education	California: Los Angeles Community College faculty	State, County and Municipal Employees	1,800
	Tennessee: Memphis Board of Education, custodial and cafeteria employees	Teachers	4,800

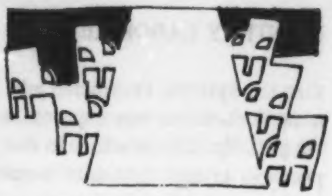
Developments in Industrial Relations



AT&T, IBEW lead communications contracts

The first round of bargaining in the telephone communicatons industry since the court-ordered breakup of the Bell System led off with a settlement between American telephone & Telegraph Co. and the International Brotherhood of Electrical Workers (IBEW). Prior to 1984, AT&T settlements with the IBEW and the Communications Workers (CWA) set a pattern for settlements between the two unions and 22 operating companies. The companies retained their identities but now are formed into seven regional firms.

Despite the auspicious leadoff settlement in the 1986 negotiations, 155,000 CWA-represented workers struck six AT&T units. The major issues leading to the stoppage reportedly were company demands for elimination of the automatic cost-of-living pay adjustment clause, elimination of incentive pay for manufacturing workers, and replacement of some high paid technicians jobs with lower paid technician assistants jobs.

AT&T and the CWA settled on national issues in mid-June, but the workers remained out pending completion of negotiations on other issues at two units. Later in the month, AT&T Information Systems and the CWA settled for 35,000 workers, following a settlement for a unit of 12,000 workers performing government work.

The 3-year IBEW contract, which was later automatically modified to contain additional terms won by the CWA, provided for four new programs to increase worker job security, reflecting their concern over the job losses resulting from the more competitive atmosphere in the communications industry following the breakup of the Bell system.

Under the first of the new programs, the company will publish annual Opportunities Outlook Reports and Placement Reports. These will inform employees about emerging jobs and qualifying knowledge and skills. The knowledge and skills will be offered under a training and retraining program financed by AT&T and administered by an AT&T-IBEW National Partnership Committee. Relevant training gained by employees under this program will be considered by the company in selecting workers for future job openings.

The third facet of increased job security is a Transfer Consideration Plan to enable workers to make their career interests and choices known to the company and to ensure that the interests and choices are considered in selecting workers for jobs. A feature of this plan is a provision permitting workers to transfer among the AT&T divisions.

The fourth approach is the establishment of an Employment Opportunities Review System under which current and laid-off employees will be informed of, and can apply for, jobs which would have been filled by new hires.

In the wage area, rates at the top of the progression schedule (which covers about 90 percent of the employees) for each grade were increased by 2 percent, intermediate steps were increased by smaller amounts, and starting rates were not changed. The increase was effective June 1, 1986, and will be followed by a May 31, 1987, and May 29, 1988, increase in rates ranging from 3 percent at the top progression step down to nothing in the starting step. All employees on the payroll at the time of an increase—including those in starting steps—were assured a raise of at least $1 a week.

The provision for automatic annual cost-of-living pay adjustments was retained in the contract but will be inoperative. Apparently, the union pressed for retention of the language to increase its chances of regaining an operating provision in the future. Under the 1983 agreements, workers represented by the IBEW (and those represented by the CWA) received adjustments in August of 1984 and 1985 totaling about $3.70 a week plus 4.5 percent of individual wage rates.

The number of pay grades was reduced to three, from 10, at manufacturing plants in Omaha, NE, Shreveport, LA, Little Rock, AR, Columbus, OH, Montgomery, IL, and Denver, CO, resulting in additional pay increases for some employees. Also, wage incentives were discontinued at these plants. In exchange, employees received lump-sum payments (up to $7,000, varying by plant location or job grade) or increases in base pay rates.

In a move to reduce costs, the parties established a "Technician Assistant" job to perform certain "menial job functions" previously performed by highly paid "Systems Technicians." The Technician Assistants will start at $200 a week and progress to $360 a week over a 30-month period. At the time of settlement, the maximum was $633 for Systems Technicians. In a related action, the parties also established a "Senior Technician" job, paying 5 percent more

---

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

than the Systems Technician job. Because a surplus of Systems Technicians was expected to develop, AT&T agreed to temporarily offer workers in the job category increases in pensions as an inducement to retire.

Other terms included—

- A 4-percent increase in pensions effective October 1, 1986, for employees retiring after May 31, 1986, and a 4-percent increase on October 1, 1988, for those retiring on or after that date.
- A 4.5-percent increase in pensions effective January 1, 1988, for all employees who retired prior to January 1, 1985. Those retiring between January 1, 1985, and January 1, 1988, will receive a prorated portion of the 4.5-percent increase.
- Addition of a new top wage bracket of $700 or more per week to the Savings and Security Plan, permitting allotments of up to $40 a week. All participants may now designate part or all of their allotment as "pre-tax" allotments under Section 401(k) of the Internal Revenue Code.
- Revision of the medical plan to cover extended health care facilities, home health care agencies, birthing centers, and chemical dependency.
- A $250 increase, to $1,000, in the annual limit on covered dental charges.

Following the settlements with AT&T, the unions' bargaining attention shifted to the seven regional operating companies and the major question was to what extent the companies would follow the terms of the AT&T accords. Contracts at the regional companies were generally scheduled to expire on August 9, 1986 (the same as the original expiration date at AT&T). Early in 1986, AT&T and the CWA and IBEW had moved their contract expiration date to May 31, 1986.

The first accord at an operating company came in late June, when Illinois Bell Telephone Co. and the IBEW settled for 12,800 installation and repair technicians, data processors, and marketing and sales employees. Bargaining was continuing for 2,300 directory assistance operators represented by the CWA.

The 3-year Illinois Bell-IBEW accord provided for an initial wage increase and a $400 lump-sum payment for an average of 2.5 percent. In the second and third years, all employees will receive 2-percent pay increases. The cost-of-living pay adjustment formula was continued, but the annual adjustments will occur only if the CPI rises more than 2 percent during a 12-month period and is subject to a 5.5-percent limit on the rise.

Other terms included—

- A "success sharing plan" under which employees will receive annual lump-sum payments of at least 1 percent (of earnings) and as much as 2 percent, using a formula based on the company's return on equity and measures of customer satisfaction.
- A 4-percent increase in pensions in 1987 and 1989.
- Continuation of job training programs that have been successful in helping make job transitions, according to the company.
- An expanded health care program called "healthchoice" offering employees the choice of a preferred provider plan that eliminate deductibles.

Illinois Bell is part of Ameritech, one of the two regional operating companies that decided to have its component companies bargain individually with the unions. The other regional company using this approach is U.S. WEST. The five regional companies bargaining as a unit with the unions were NYNEX, Bell South, Bell Atlantic, Pacific Telesis, and Southwestern Bell.

Auto Workers, Caterpillar agree on concessions

The Auto Workers agreed to a 28-month contract with Caterpillar, Inc., that essentally froze wages and included changes in the job structure intended to hold down labor costs, despite an increase in profits at the company. (Caterpillar earned a $139 million profit during the second quarter of 1986, up from $50 million in the second quarter of 1985.) In return, Caterpillar agreed to establish a job security program and an employee development and training program to help reduce the number of workers on layoff. The accord covered 16,600 active and 13,000 laid-off workers in six States. Much of Caterpillar's problems in selling its construction equipment and diesel engines result from increasing penetration of U.S. market by foreign manufacturers.

Under the new Protected Employee Group program, 90 percent of the employees in the bargaining unit will be protected against layoffs resulting from economic conditions or marketplace changes, "sourcing" decisions, introduction of new technology, productivity improvements, and consolidation of operations. Exclusions from the job guarantee include temporary layoffs of up to 6 weeks a year; work force cuts resulting from labor disputes or sale or cessation of operations; and layoffs resulting from events beyond the company's control. Caterpillar will commit a total of $21 million to this program and to the job retraining program, which will also use any available financial support from Federal and State governments.

The retraining program is aimed at providing new skills for workers. It will particularly aid senior employees who in the past might have been laid off because they lacked skills needed to move into other jobs. Reportedly, 1,000 to 1,200 of such laid-off employees will be retrained and rehired during the next 18 months.

The provisions for automatic quarterly cost-of-living pay adjustments was continued at 1-cent-an-hour for each 0.26-point movement in the BLS CPI-W (1967=100), subject to a total diversion of 23 cents an hour over the term. The diverted money will be used to help pay for the job training program and other contract provisions.

Current employees will receive a $180 immediate lump-sum payment, and those returning from layoff by July 10, 1987, will receive this payment when they resume work.

For current employees, normal pension rates were increased by $3.05 a month for each year of credited service; the "30-and-out" pension was increased to as much as $1,205 a month; and, if Caterpillar requests employees to retire early to reduce employment levels, the company has the option of adding a $300 a month inducement to regular early pensions. All current retirees will receive a $1 a month increase in their benefit rate plus $200 payments in December of 1986 and 1987.

Other provisions included a 4-cent-an-hour increase in the company's maximum financing of Supplemental Unemployment Benefits, which will help to eliminate the reduction in benefits being suffered by laid-off employees because of the large number drawing from the fund; an additional paid holiday, the birthday of Dr. Martin Luther King, Jr.; and changes in the profit-sharing plan that will raise payouts by 75 percent, according to the union.

Elsewhere in the industry, Deere & Co. and the Auto Workers agreed to extend their contract to October 17, 1986, from May 30, 1986, to await the outcome of the Caterpillar talks. (After the Caterpillar settlement, Deere and the UAW changed their expiration date to late August.) Deere, the Nation's largest farm equipment manufacturer, reported a $33.4 million loss during the quarter ending April 30, and was in the process of reducing operations. The union's contracts with J.I. Case Co. for its original farm equipment operations and for those it purchased from International Harvester Co. (now Navistar International Corp.) in 1985 expire in February 1987. Navistar now manufacturers only trucks. Its contract with the Auto Workers was scheduled to expire September 30, 1986.

Strike against Weyerhaeuser ends

A 6-week strike against Weyerhaeuser Co.'s forest product operations in Oregon and Washington ended when members of two unions approved new contracts that cut wages more than 20 percent. One of the unions, the Woodworkers, settled first for 6,200 employees it represents at logging operations, followed by the Lumber Production and Industrial Workers unit of the Carpenters union, which agreed to similar terms for 1,000 workers it represents at lumber mills. It was not immediately clear if other forest products firms in the Pacific Northwest would settle with the unions on similar terms, reflecting the difficulties the employers (and employees) have been experiencing in recent years as a result of increasing competition from lower cost operators in the region, in the South, and in Canada.

The 2-year Weyerhaeuser contract calls for an average pay cut of $2.90 an hour and benefit cuts of about $1. Prior to the settlements, mill workers averaged $18.19 an hour in wages and benefits and loggers averaged $22.36, according to the company.

The compensation cut was about the same as in an earlier company offer the workers had overwhelmingly rejected. A major difference that influenced the vote on the second accord was the dropping of a company proposal that promotions and job retention be based on employee "competence," rather than seniority.

During the last 20 years, collective bargaining had been relatively stable in the industry, with the larger companies settling with the unions on uniform terms that were then extended to other companies. In 1983, the larger companies and the unions agreed on a wage and benefit package, but Louisiana-Pacific Corp. refused to follow the pattern and countered a union strike by hiring replacements and continuing operations. Eventually, the unions lost the right to represent workers at the company's western operations. In late 1985, Potlatch Corp. closed certain unprofitable operations in Idaho, reopening them only after 850 members of the Woodworkers union agreed to compensation cuts.

The 1986 round of bargaining was drastically changed when the pattern-setting Western States Wood Products Employers Association (also known as the "Big Seven") broke up and announced that the companies would bargain individually, and in some cases, on a mill-by-mill basis.

To counter this fragmented approach, the two unions attempted to coordinate their bargaining efforts and demands by forming a Forest Products Joint Bargaining Board. One of the Board's goals was to move toward eliminating the compensation differential between regions by winning larger increases for southern workers in negotiations scheduled for 1987.

Copper industry gains labor costs reductions

The copper mining and processing industry, plagued by severe financial problems resulting from worldwide overproduction, gained some reductions in labor costs in midyear settlements. Kennecott, the domestic industry's largest producer, indicated that lower costs would enable it to reopen its large Bingham Canyon, UT, mine and recall 2,000 employees who lost their jobs when operations shut down in 1985. The 14 unions attempted to tailor each of the copper accords to the condition of the company. The unions, led by the Steelworkers, comprised the Nonferrous Industry Coordinating Committee. About 8,000 active and 5,000 laid-off workers were covered by the settlements, compared with about 25,000 active employees in the late 1970's.

The first settlement, which occurred just before the contract expiration date for all the major companies, involved 3,000 employees of Newmont Mining Corp.'s Magma Copper Co. and Pinto Valley Copper Co. facilities in Arizona. It provided for a pay cut of 20 percent, resulting in hourly rate ranges of $9 to $12.60 at Magma and $8.88 to $13 at Pinto Valley. The cut, which reportedly averaged $2.82 an hour, could be alleviated or eliminated under a new bonus plan contingent on rises in copper prices. In 1987, the quarterly payments will be calculated at 10 cents per hour for each one-cent rise in the price of a pound of copper above 70 cents, an extra 15 cents for each one-cent rise above 80 cents, and an additional 25 cents for each one-cent rise above 90 cents, up to $1. In 1988, the formula will be 15 cents for each one-cent rise from 71 to 90 cents and 25 cents for each one-cent rise from 91 cents to $1. Employees may take the money in cash or in a 401(k) savings plan, or a combination of the two. At the time of settlement, the price of copper was 63 cents a pound.

Other wage terms included termination of the provision for automatic cost-of-living pay adjustments, which had provided the only pay increase under the prior contract.

Benefits also were standardized at the two companies, resulting in pension improvements at Magma and health insurance improvements at Pinto Valley. A new health insurance cost containment plan requires deductible and co-insurance payments by the workers.

Newmont estimated that the employee sacrifices would cut labor costs to less than 50 percent of production costs, from 52 percent. The company lost $34.2 million in 1985.

The second settlement in the bargaining round involved 1,650 ASARCO employees who agreed to a 3-year contract that called for an initial wage cut of $3.50 an hour. In the second year, there will be a 75-cent-an-hour wage increase, followed by a $1 increase in the final year. As at Newmont, the cost-of-living provision was terminated. Benefits were unchanged, except for adoption of annual health insurance deductibles of $100 for single employees and $300 for families. The ASARCO operations are located in Texas, Arizona, Washington, and New Jersey.

Kennecott Corp. took the firmest stand against the unions, contending that it required a larger cut than the other companies because its compensation levels were $4-$5 an hour higher. Kennecott said its wage and benefit costs averaged $24 an hour, and asked for an $8 reduction.

Under the 4-year contract, compensation was reduced by $5.40 an hour or about 22 percent. The wage portion of compensation, which averaged about $13.50, was cut an average of $3.22. Cost-of-living adjustments also were terminated. The terms for the 1,500 active and 5,000 laid-off employees included a $1,000 lump-sum payment to active employees within 60 days.

Employees will now be required to pay 20 percent of health insurance premium costs and $350 annual deductibles if they are single and $700 if married. Deductibles also were instituted for dental coverage, vision coverage was eliminated, vacation pay was reduced, and a number of local contracts were consolidated to cut costs by eliminating or changing work rules. At the time of settlement, Kennecott reportedly had 1,500 contracts with 41 local unions.

Another major producer, Phelps Dodge Corp., was not involved in the negotiations because the unions were decertified as bargaining agents earlier in the year. The events leading to the employee vote to terminate union representation began in 1983, when Phelps Dodge refused to accept the settlement pattern of the other companies, leading to a strike that eventually proved unsuccessful as the company moved toward full output by hiring replacement workers.

Alcoa-Reynolds contracts

In similar settlements, the Aluminum Co. of America and Reynolds Metals Co. gained some labor cost reductions from the United Steelworkers and the Aluminum, Brick and Glass Workers, but the reductions were less than that negotiated last year by Kaiser Aluminum and Chemicals Corp. (See *Monthly Labor Review*, June 1985, p. 50.)

The new Alcoa-Reynolds contracts provide for a 95-cent-an-hour reduction in labor compensation, which reportedly totaled about $24, including $13 in pay. Both unions agreed to eliminate extended vacations—10 weeks of paid time off employees had received once every 7 years instead of the regular annual vacation for that year. (Employees will be paid for the amount of time off they had accrued at the time of termination.) The unions also agreed to eliminate vacation bonuses—amounts ranging from $30 to $112.50 per week (varying by the time of year when vacation is taken) added to regular vacation pay as an inducement to vacation at times other than the traditional summer months. (This provision had been suspended during the final 2 years of the 1983 contracts.)

The balance of the 95-cent reduction was attained differently by the two unions. For employees represented by the Steelworkers, changes included reducing the existing cost-of-living pay allowance to 32.6 cents, from 63 cents. For employees represented by the Aluminum Workers, only 2.4 cents was cut from the 56-cent cost-of-living allowance, but they gave up a $700 annual allocation from the company that had been used to cover their health insurance deductible and co-insurance payments, with any unused portion of the $700 paid to them at yearend.

There was no provision for specified wage increases, but both contracts provided for the continuation of quarterly cost-of-living adjustments, calculated at 1-cent-an-hour for each 0.3-index point rise in the BLS CPI-W (1967=100) in excess of 3 percent a year. Previously, the calculation rate was 1 cent for each 0.26-point rise in excess of 2.3 percent a year for the Aluminum Workers and in excess of 1.5 percent a year for the Steelworkers.

All four agreements provide for joint committees to consider the possibility of establishing profit-sharing plans.

The Aluminum Workers represent 8,000 workers at Alcoa and 6,000 at Reynolds, and the Steelworkers represent 7,000 at Alcoa and 3,600 at Reynolds. The unions, which coordinated their bargaining, began a walkout on June 1, but limited it to Alcoa because of the company's "belligerent attitude" and because it is the "major company in the industry," according to a Steelworkers official. Members of both unions began returning to work after a tentative settlement on July 2. In Massena, NY, and Warrick, IN, 3,500 Aluminum Workers stayed out longer over local issues.

States not allowed to quit Social Security system

A recent decision of the Supreme Court held that States may not pull their employees out of the Social Security system. The case was initiated by the State of California, several State agencies, taxpayers, and a group called Public Agencies Opposed to Social Security Entrapment, which challenged a 1983 law prohibiting a State or any of its agencies from withdrawing from the system. The parties contended that the amendment to the Social Security Act violated a 1951 amendment that gave them the right to stay outside the system and, if they joined, to withdraw after 10 years' participation, after giving 2 years' notice. The amendment negated notices California had filed on behalf of about 70 political units for 34,000 employees.

In the unanimous opinion, written by Justice Lewis F. Powell, Jr., the Court said the 1983 law "simply was part of a regulatory program over which Congress retained authority to amend in the exercise of its power to provide for the general welfare."

In seeking a review of a Federal district judge's finding that the amendment was unconstitutional, the Federal Government had argued that the benefit rights of 9 million State and local government employees would be threatened if such withdrawals were permitted, and that the entire system would be threatened if such withdrawals were permitted to continue. Government entities that have withdrawn or attempted to withdraw have contended they could obtain better benefits at lower costs by other means, such as State-backed pension plans.

The decision in the case, *Bowen, Secretary of Health and Human Services et al vs. Public Agencies Opposed to Social Security Entrapment et al,* does not apply to political units not now in the system, unless they choose to join.

Supreme Court hears sexual harassment case

The Supreme Court unanimously ruled that sexual harassment of an employee by a supervisor violates Title 7 of the Civil Rights Act of 1964, which prohibits racial and sexual discrimination. In one opinion, written by Justice William H. Rehnquist and joined by four other justices, the Court held that sexual harassment that is "sufficiently severe or pervasive" to create "a hostile or abusive work environment" is a violation even if the sexual demands are not tied to employment benefits.

However, Rehnquist said companies are not "always automatically liable for sexual harassment by their supervisors." According to his reasoning, an employer's lack of knowledge of sexual harassment by a supervisor "does not necessarily insulate that employer from liability," but he did not issue a precise rule on employer liability. Rehnquist also said the appellate court had erred in prohibiting the defendant from presenting testimony intended to show that the employee's dress and conversation invited advances by the supervisor.

Justice Thurgood Marshall, joined by three other justices, agreed that "workplace sexual harassment is illegal," but disagreed on the issue of employer liability. Marshall contended that employers should be held liable for sexual harassment by their employees "regardless of lack of knowledge or any other mitigating factor." This position, which backed the guidelines adopted by the Equal Employment Opportunity Commission (EEOC) in 1980, was opposed by the present EEOC and the Department of Justice. In a joint brief, they argued that penalties should be imposed only on employers who know or should know of sexually offensive conditions or who do not provide reasonable means for bringing complaints to the employers' attention and seek remedies.

The case, *Meritor Savings Bank v. Vinson,* arose when Mechelle Vinson accused her supervisor, Sidney L. Taylor, of pressuring her into a sexual relationship. Taylor denied the charge, and the Washington, DC, bank contended that it was not aware of any sexual harassment by Taylor. A federal district judge ruled in favor of the defendants, but this decision was reversed by the U.S. Court of Appeals for the District of Columbia, leading to the Supreme Court appeal.

Military pension formula revised

President Ronald Reagan signed the Military Retirement Reform Act of 1986, intended to induce members of the Armed Forces to prolong their careers by revising the pension formula. The new formula applies to people entering the Armed Forces after August 1, 1986, and attaining the existing minimum 20 years' service required for normal retirement.

Under the new formula, those retiring at or after age 62 with 20 years' service will receive a pension equal to 40 percent of their average annual basic pay during their highest three consecutive years. Those with longer service will receive an additional 2.5 percent of the average annual basic pay figure for each year in excess of 20, up to a maximum pension of 75 percent after 30 years or more of service.

Those retiring before age 62 will receive a benefit ranging from 40 percent for 20 years' service to 75 percent for 30 years. When these retirees attain age 62, their pensions will automatically increase to the amount they would have received by retiring at age 62 with the same length of service.

In another change, service members retiring before age 62 will receive automatic annual percentage adjustments in their pension equal to any rise in the BLS-Consumer Price

Index over a 12-month period, less 1 percentage point. On attaining age 62, their benefit rate will be restored to the amount they would have received if the 1-percentage point withholding had not occurred. Thereafter, any annual increases under the provision will again be reduced by 1 percentage point.

Those retiring at age 62 or later will continue to receive the full amount of any annual increases. Previously, all retirees received the full amount of any annual increases, regardless of age.

Previously, age was not a factor in calculating pensions, which ranged from 50 percent after 20 years service to 75 percent after 30 years or more.

New York City imposes residency requirements

New York City joined the list of cities imposing residency requirements on municipal employees when the city council approved a bill requiring employees hired on or after September 1, 1986, to be residents or to move into the city within 90 days. Ultimately, the requirement will apply to 80,000 city employees. It does not apply to 180,000 employees in the city's uniformed services or in independent agencies created by the State.

In 1978, the city council had adopted a bill requiring all municipal employees to reside in the city. However, in 1980 the State's Court of Appeals held that the city did not have jurisdiction over the independent agencies and that the city's law was superseded by a State law requiring the uniformed employees to reside in the city's five boroughs or in six nearby New York counties.

While the city council was approving the new 1986 residency requirement, the State legislature approved a bill permitting uniformed employees who have been living in New York State but outside of New York City and the six nearby counties to remain where they are. The bill also requires city employees living outside the State to move into the metropolitan area within 1 year. Those hired for the uniformed services in the future will have to reside in the city or the six nearby counties.

A number of major cities have adopted employee residency requirements, including Boston, Philadelphia, Chicago, Detroit, Cleveland, and Buffalo. Generally, backers contend such requirements are proper because the employees serve the public better if they reside where they work, the employees are more readily available for emergency situations, and they aid the city's economy by spending part of their pay locally.

Critics generally contend that residency requirements unfairly limit where employees may live and are particularly onerous for low-income employees.

Hospital contracts

A 3-month strike against hospitals in Kentucky, West Virginia, and Virginia ended when members of the United Steelworkers union approved a 3-year contract with the Appalachian Regional Hospitals, operator of the nine institutions (employees remained on strike at another institution in Man, wv). Two of the hospitals settled in mid-June, and the others settled at the end of the month, breaking the tradition of negotiating master contracts covering all 10 hospitals.

Wage terms were the same at all locations: an increase of 3.9 percent or an average of 28 cents an hour in the first year, 3.7 percent or 26 cents in the second year, and 3.5 percent or 25 cents in the final year.

There were no changes in benefits, but there were numerous changes in job bumping, seniority, and absenteeism provisions. According to an official of the hospital agency, some of the 1,850 licensed practical nurses and clerical, technical, and service employees might not be recalled because the hospitals operated efficiently during the stoppage and some patients had been lost to competing hospitals.

In Philadelphia, 5,000 workers engaged in sit-down strikes lasting about 4 hours before settling with eight hospitals and several clinics. The nurses, aides, orderlies, and other employees won wage increases of 5 percent in the first year, 4 percent in the second year, and 3 percent in the final year. Prior to the settlement, pay reportedly averaged $8.50 an hour.

Benefit changes negotiated by the National Union of Hospital and Health Care Employees include a reduction in the surcharge the hospitals had been applying to employees' medical bills in order to cut a fund surplus; a 12.2-percent (of payroll) employer payment to the fund (formerly 12 percent), subject to a further increase in the third year if required to maintain current benefit levels; adoption of a program to contain cost increases for medical care; and adoption of a preferred provider organization among the hospitals guaranteeing that workers will be treated without cost in the hospital where they are employed.

The union said that hospitals also generally agreed to a number of "social" demands, such as giving 6 months' notice of cuts or elimination of service; formation of joint committees to find alternative uses for underutilized beds; giving union and community leaders a voice in adding or terminating hospital services; prohibiting volunteers from performing duties of employees in the bargaining unit; and establishing committees to control the use of part-time employees.

Food and Commercial Workers settlements

In New York State, a 3-year settlement between P&C Food Markets, Inc., and United Food and Commercial Workers Local 1 does not provide for a wage increase in the first year, but the 4,200 workers will receive lump-sum payments later. The payments—quarterly in the second year and semiannual in the third—will be calculated at 30 cents for each work, vacation, and holiday hour for full-time employees and at 15 cents for part-time employees. At the time of settlement, pay rates were $11.85 an hour for top-rated meatcutters. Top rates for clerks were $10.325 an hour for those hired before May 23, 1983, and $8.80 for those hired later.

Cost-reducing changes won by the 66 stores included elimination of the cost-of-living pay adjustment clause; reduced premium pay for some holiday, weekend, and overtime work; and eligibility of part-timers for health insurance after 6 months' service (formerly 3 months).

In north central Pennsylvania, the United Food and Commercial Workers and Riverside Supermarkets agreed on wage cuts in exchange for a moratorium on closing any of the 22 stores during the 3-year contract term. The company had closed 20 stores and laid off 1,800 employees during the last 2 years, citing intense competition from nonunion grocery stores with lower labor costs.

The maximum pay cut of 89 cents an hour (to $11.03) applied to meat department managers. The cut was 77 cents (to $9.64) for top-rated meat cutters, and 69 cents (to $8.63) for top rated grocery clerks. Pay was not reduced for workers in the lowest grades.

All employees except courtesy clerks will receive 10-cent wage increases in May and November of 1988.

Job and wage security provided for New UPI workers

New UPI, Inc., the successor to financially troubled United Press International, negotiated a 1-year contract that provides job and wage protection for the 750 employees remaining in the bargaining unit. Since 1984, when the union agreed to a 25-percent pay cut to aid the news service, which is operating under protection of the bankruptcy court, hundreds of employees have lost their jobs.

Under the accord, which expires April 20, 1987, wages are set at 105 percent of the levels in effect immediately prior to the cut; company debts to the union and the employees will be paid in full (compared with 40 percent to most other creditors); the company will not reduce the number of full-time permanent employees in the unit during the agreement term, and will consider the possibility of increasing the work force; a profit-sharing plan will be established; and the company will invest $15 million in new equipment over the next 2½ years. ☐

ERRATA

In the research summary "Displaced workers: one year later," which appeared in the July issue, the last sentence beginning on p. 40 contains an incorrect figure. The sentence should read:

> Among the unemployed of January 1984, 50 percent or more of both white and Hispanic workers were employed in 1985, compared with 42 percent of black workers.

In table 2, p. 41, two labor force classifications were transposed (the data are correct as shown). The top classification of the second category should read "From unemployed to—" and the top classification of the third category "From not in labor force to—." The correct table appears below.

Table 2. Labor force transition rates for displaced workers by sex, race, and Hispanic origin, January 1984 to January 1985
[Percent]

Labor force category	Displaced workers, 20 years and over[1]						Others, 20 years and over
	Total	Men	Women	White	Black	Hispanic origin[2]	
From employed to—							
Employed	87.9	88.8	85.9	87.8	88.1	80.8	89.4
Unemployed	7.8	9.2	4.6	7.7	8.4	11.5	3.0
Not in labor force	4.3	1.8	9.5	4.5	3.5	8.5	7.6
From unemployed to—							
Employed	53.0	53.5	52.1	55.3	42.4	50.0	47.8
Unemployed	27.5	31.8	18.7	24.3	42.4	15.0	26.3
Not in labor force	19.5	14.6	28.8	20.3	15.2	35.0	25.9
From not in labor force to—							
Employed	19.8	17.1	21.8	19.5	15.3	32.0	10.8
Unemployed	5.5	8.9	2.7	4.2	12.6	4.0	2.5
Not in labor force	74.8	73.7	75.5	76.3	72.1	64.0	86.7

[1] Data refer to persons age 20 and over with tenure of 3 years or more who lost or left a job between January 1979 and January 1984 because of plant closings or moves, slack work, or the abolishment of their positions or shifts.

[2] Hispanics are included in both the white and black population groups.

NOTE: The transition rate represents the proportion of workers in the first labor force category in January 1984 who were in the second labor force category in January 1985.

Book Reviews

Building bridges

Employing Bureaucracy: Managers, Unions, and the Transformation of Work in American Industry, 1900–1945. By Sanford M. Jacoby. New York, Columbia University Press, 1985. 377 pp. $35.

In the late 1970's, many industrial relations scholars proclaimed that labor history and industrial relations had little in common, and that the former was of little use in formulating public policy. Cross-disciplinary interest in labor and economic history, however, has experienced a marked revival in popularity, most recently exemplified by the joint sessions held at the respective annual meetings of the Industrial Relations Research Association and the American Historical Association. Sanford M. Jacoby, Professor of Industrial Relations at the UCLA Graduate School of Management, has contributed to the revival with this excellent historical analysis of the evolution of the American labor market through the interactions of employers, workers, and the Federal Government. Jacoby states that a primary purpose of this book is "to rebuild the bridge between labor economics and economic history."

Jacoby takes the reader on a chronological journey that begins before the turn of the century through the World War II period, analyzing the macroeconomic, social, and political forces that influenced and directed our internal labor market. The first chapters revolve around efforts to stabilize industry in the late 19th and early 20th centuries, acknowledged as the formative period of modern industrial capitalism, through social and economic planning. Industrial engineers, social welfare workers, political reformers, liberal trade unionists, and progressive employers led this search for order by focusing on the problems of American workers—job alienation, unemployment and job security, labor turnover and unrest—and in implementing corrective workplace innovations—employee stock ownership plans, work-sharing plans, pension plans, and fringe benefits. This collectively fit under the umbrella of personnel management, a fairly new and unwelcomed concept to the generic employer of the early 1900's. In fact, it took the crises of war and depression, thoroughly covered in the second segment of the book, to dislodge most employers from a market oriented and incongruous employment system to a professional personnel management structure as an intrinsic part of corporate employment policy.

Between world conflict and economic malaise, the average employer unsuccessfully fought for a regression to the status quo of pre-World War I. At the center of this struggle was the factory foreman, and Jacoby highlights his metamorphosis from shop floor autocrat to marginal manager in the production process. He also illustrates that foremen allied with production and marketing managers in opposition to the new managerial order and for retention of the production oriented but dehumanizing "drive system" of labor relations. As Jacoby also notes, the wounds of propersonnel management advocates were often self-inflicted; philosophical divisions within ranks were deleterious to the cause.

The central theme of *Employing Bureaucracy* is that the transformation of the workplace was not the result of a free labor market but a reaction to it. Sophisticated personnel practices (that is, structured work rules, job classifications, and other bureaucratic facets of corporate employment policy) developed from employer responses to trade union pressures and equitable government legislation. For example, Jacoby illustrates that personnel departments flourished following enactment of the National Industrial Recovery Act (NRA), and subsequent Wagner Act, in direct correlation to the institutionalization of collective bargaining through the labor adjustment machinery created by the legislation; this followed patterns set in the World War I period, when similar adjustment mechanisms tried to prevent production defeating disputes in a tight labor market.

In tracing the evolution of this phase of the work process, the author provides a well constructed and meticulously researched narrative on the related segments of trade unionism, welfare capitalism, Taylorism, and vocational education. If you want to read about ethno-cultural divisions in the workplace, rank and file militancy, or class collaboration, you will have to look elsewhere. Jacoby eschews Marxist and other radical theories for traditional industrial relations history. Undoubtedly, some reviewers will criticize this and cite the lack of new information or theory as shortcomings of the book. But, while some information has been studied and published previously, the holistic value of the work is significant. With the exception of works like Daniel Nelson's *Workers and Managers: Origins of the New Factory System in the United States,* labor history has lacked this type of study in recent years.

It would have been interesting if Jacoby had touched on and at least compared the theories of more radical labor scholars to his own, for example, in regard to some of the Keynesian-corporatist paradigms postulated in explaining the failure of true working class solidarity in the United States. If there is criticism of the book, this would have to be included as a minor point. *Employing Bureaucracy,* therefore, should be read in conjunction with such neo-Marxist interpretations as *Segmented Work, Divided Workers,* by Daniel Gordon, Richard Edwards, and Michael Reich. A good non-Marxist complement to the book, analyzing some of the same material, is *The Second Industrial Divide* by Michael Piore and Charles Sabel.

As the author notes, history is an imperfect guide for public policy, but any study of labor market transitions without institutional memory is seriously flawed. In an alleged era of industrial transition marked by concessionary negotiations, employer demands for more flexible work patterns, and worker participation in managerial decisionmaking, industrial relations policymakers should understand that these are all products of a historical progression. Labor's house has many rooms, but in recent years access between them has been blocked. Perhaps this book will help to open some doors, even if few scholars choose to enter.

ERRATA

In "Labor and management continue to comb mutual problems," by George Ruben, *Monthly Lab Review*, January 1986, the discussion of the contra between the Clothing and Textile Workers Union a the shirt, cotton garments, and pants industry contai incorrect dates (page 9, second column, four paragraph). The second sentence should read:

> The 3-year accord provided for a lump-sum payment of $500 by December of 1985,followed by payments in December of 1986 and 1987 equal to 6.5 percent of individual employee's earnings (exclusive of any lump-sum payment) during the preceding 12 months.

The contract between the Clothing and Texti Workers Union and the men's and boys' tailor clothing industry was for 2 years, not 3 years reported in the article.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force, employment, unemployment, collective bargaining settlements, consumer, producer, and international prices, productivity, international comparisons, and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described, key definitions are given, notes on the data are set forth, and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. (Seasonally adjusted data appear in tables 1–3, 4–10, 13, 14, 17, and 18.) Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are seasonally adjusted with a procedure called X–11 ARIMA, which was developed at Statistics Canada as an extension of the standard X–11 method previously used by BLS. A detailed description of the procedure appears in *The X–11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada, Catalogue No. 12–564E, February 1980). The second change is that seasonal factors are calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at midyear for the July-December period. However, revisions of historical data continue to be made only at the end of each calendar year.

Seasonally adjusted labor force data in tables 1 and 4–10 were revised in the February 1986 issue of the *Review*, to reflect experience through 1985.

Annual revisions of the seasonally adjusted payroll data shown in tables 13, 14, and 18 were made in the July 1986 *Review* using the X–11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in table 42 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the Hourly Earnings Index in table 17—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The $2 (or any other resulting values) are described as "real," "constant," or "1967" dollars.

Additional information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule preceding these general notes. More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in *Employment and Earnings*, a monthly publication of the Bureau. More data from the household survey are published in the two-volume data book—*Labor Force Statistics Derived From the Current Population Survey*, Bulletin 2096. More data from the establishment survey appear in two data books—*Employment, Hours, and Earnings, United States*, and *Employment, Hours, and Earnings, States and Areas*, and the annual supplements to these data books. More detailed information on employee compensation and collective bargaining settlements is published in the monthly periodical, *Current Wage Developments*. More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report*, and *Producer Prices and Price Indexes*. Detailed data on all of the series in this section are provided in the *Handbook of Labor Statistics*, which is published biennally by the Bureau. BLS bulletins are issued covering productivity, injury and illness, and other data in this section. Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.
n.e.s. = not elsewhere specified.

COMPARATIVE INDICATORS
(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-to-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonagricultural payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in: consumer prices for all urban consumers; producer prices by stage of processing; and the overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data. For detailed descriptions of each data series, see BLS *Handbook of Methods*, Volumes I and II, Bulletins 2134–1 and 2134–2 (Bureau of Labor Statistics, 1982 and 1984, respectively), as well as the additional bulletins, articles, and other publications noted in the separate sections of the *Review*'s "Current Labor Statistics Notes." Historical data for many series are provided in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). Users may also wish to consult *Major Programs, Bureau of Labor Statistics*, Report 718 (Bureau of Labor Statistics, 1985).

EMPLOYMENT DATA

(Tables 1; 4–21)

Household survey data

Description of the series

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 59,500 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all civilians who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. Members of the Armed Forces stationed in the United States are also included in the employed total. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **overall unemployment rate** represents the number unemployed as a percent of the labor force, including the resident Armed Forces. The **civilian unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **labor force** consists of all employed or unemployed civilians plus members of the Armed Forces stationed in the United States. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons who are retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy, and members of the Armed Forces stationed in the United States. The **labor force participation rate** is the proportion of the noninstitutional populaton that is in the labor force. The **employment-population ratio** is total employment (including the resident Armed Forces) as a percent of the noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 4–10 are seasonally adjusted, based on the seasonal experience through December 1985.

Additional sources of information

For detailed explanations of the data, see BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 1, and for additional data, *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). A detailed description of the Current Population Survey as well as additional data are available in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*. Historical data from 1948 to 1981 are available in *Labor Force Statistics Derived from the Current Population Survey: A Databook*, Vols. I and II, Bulletin 2096 (Bureau of Labor Statistics, 1982).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Establishment survey data

Description of the series

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by more than 250,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include working supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12–17 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in the following industries: transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and

services. These groups account for about four-fifths of the total employment on private nonagricutural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earner and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index, introduced in the May 1983 *Review*, represents the percent of 185 nonagricultural industries in which employment was rising over the indicated period. One-half of the industries with unchanged employment are counted as rising. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. The diffusion index is useful for measuring the dispersion of economic gains or losses and is also an economic indicator.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1986 data, published in the July 1986 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Unadjusted data have been revised back to April 1984; seasonally adjusted data have been revised back to January 1981. These revisions were published in the *Supplement to Employment and Earnings* (Bureau of Labor Statistics, 1986). Unadjusted data from April 1985 forward, and seasonally adjusted data from January 1982 forward are subject to revision in future benchmarks.

In the establishment survey, estimates for the 2 most recent months are based on incomplete returns and are published as preliminary in the tables (13 to 16 in the *Review*). When all returns have been received, the estimates are revised and published as final in the third month of their appearance. Thus, August data are published as preliminary in October and November and as final in December. For the same reason, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Thus, second quarter data are published as preliminary in August and September and as final in October.

Additional sources of information

Detailed data from the establishment survey are published monthly in the BLS periodical, *Employment and Earnings*. Earlier comparable unadjusted and seasonally adjusted data are published in *Employment, Hours, and Earnings, United States, 1909–84*, Bulletin 1312–12 (Bureau of Labor Statistics, 1985) and its annual supplement. For a detailed discussion of the methodology of the survey, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 2. For additional data, see *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Unemployment data by State

Description of the series

Data presented in this section are obtained from two major sources—the Current Population Survey (CPS) and the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act and the Public Works and Economic Development Act. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for 11 States—California, Florida, Illinois, Massachusetts, Michigan, New York, New Jersey, North Carolina, Ohio, Pennsylvania, and Texas—are obtained directly from the CPS, because the size of the sample is large enough to meet BLS standards of reliability. Data for the remaining 39 States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates for the 11 States are revised to new population controls. For the remaining States and the District of Columbia, data are benchmarked to annual average CPS levels.

Additional sources of information

Information on the concepts, definitions, and technical procedures used to develop labor force data for States and sub-State areas as well as additional data on sub-States are provided in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*, and the annual report, *Geographic Profile of Employment and Unemployment* (Bureau of Labor Statistics). See also *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 4.

COMPENSATION AND WAGE DATA

(Tables 1–3; 22–29)

COMPENSATION AND WAGE DATA are gathered by the Bureau from business establishments, State and local governments, labor unions, collective bargaining agreements on file with the Bureau, and secondary sources.

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It uses a fixed market basket of labor—similar in concept to the Consumer Price Index's fixed market basket of goods and services—to measure change over time in employer costs of employing labor. The index is not seasonally adjusted.

Statistical series on total compensation costs and on wages and salaries are available for private nonfarm workers excluding proprietors, the self-employed, and household workers. Both series are also available for State and local government workers and for the civilian nonfarm economy, which consists of private industry and State and local government workers combined. Federal workers are excluded.

The Employment Cost Index probability sample consists of about 2,200 private nonfarm establishments providing about 12,000 occupational observations and 700 State and local government establishments providing

3,500 occupational observations selected to represent total employment in each sector. On average, each reporting unit provides wage and compensation information on five well-specified occupations. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Fixed employment weights from the 1980 Census of Population are used each quarter to calculate the indexes for civilian, private, and State and local governments. These fixed weights, also used to derive all of the industry and occupation series indexes, ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the bargaining status, region, and metropolitan/nonmetropolitan area series, however, employment data by industry and occupation are not available from the census. Instead, the 1980 employment weights are reallocated within these series each quarter based on the current sample. Therefore, these indexes are not strictly comparable to those for the aggregate, industry, and occupation series.

Definitions

Total compensation costs include wages, salaries, and the employer costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as social security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980 to produce, when combined with the wages and salaries series, a measure of the percent change in employer costs for employee total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the *civilian* nonfarm economy (excluding Federal employees). Historical indexes (June 1981=100) of the quarterly rates of change are presented in the May issue of the BLS monthly periodical, *Current Wage Developments*.

Additional sources of information

For a more detailed discussion of the Employment Cost Index, see the *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 11, and the following *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor'," July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; "Estimation procedures for the Employment Cost Index," May 1982; and "Introducing new weights for the Employment Cost Index," June 1985.

Data on the ECI are also available in BLS quarterly press releases issued in the month following the reference months of March, June, September, and December; and from the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Collective bargaining settlements

Description of the series

Collective bargaining settlements data provide statistical measures of negotiated adjustments (increases, decreases, and freezes) in compensation (wages and benefits costs) and wages alone, quarterly for private industry and semiannually for State and local government. Compensation measures cover all collective bargaining situations involving 5,000 workers or more and wage measures cover all situations involving 1,000 workers or more. These data, covering private nonagricultural industries and State and local governments, are calculated using information obtained from bargaining agreements on file with the Bureau, parties to the agreements, and secondary sources, such as newspaper accounts. The data are not seasonally adjusted.

Settlement data are measured in terms of future specified adjustments: those that will occur within 12 months after contract ratification—first year—and all adjustments that will occur over the life of the contract expressed as an average annual rate. Adjustments are worker weighted. Both first-year and over-the-life measures exclude wage changes that may occur under cost-of-living clauses that are triggered by future movements in the Consumer Price Index.

Effective wage adjustments measure all adjustments occurring in the reference period, regardless of the settlement date. Included are changes from settlements reached during the period, changes deferred from contracts negotiated in earlier periods, and changes under cost-of-living adjustment clauses. Each wage change is worker weighted. The changes are prorated over all workers under agreements during the reference period yielding the average adjustment.

Definitions

Wage rate changes are calculated by dividing newly negotiated wages by the average hourly earnings, excluding overtime, at the time the agreement is reached. Compensation changes are calculated by dividing the change in the value of the newly negotiated wage and benefit package by existing average hourly compensation, which includes the cost of previously negotiated benefits, legally required social insurance programs, and average hourly earnings.

Compensation changes are calculated by placing a value on the benefit portion of the settlements at the time they are reached. The cost estimates are based on the assumption that conditions existing at the time of settlement (for example, methods of financing pensions or composition of labor force) will remain constant. The data, therefore, are measures of negotiated changes and not of total changes in employer cost.

Contract duration runs from the effective date of the agreement to the expiration date or first wage reopening date, if applicable. Average annual percent changes over the contract term take account of the compounding of successive changes.

Notes on the data

Care should be exercised in comparing the size and nature of the settlements in State and local government with those in the private sector because of differences in bargaining practices and settlement characteristics. A principal difference is the incidence of cost-of-living adjustment (COLA) clauses which cover only about 2 percent of workers under a few local government settlements, but cover 50 percent of workers under private sector settlements. Agreements without COLA's tend to provide larger specified wage increases than those with COLA's. Another difference is that State and local government bargaining frequently excludes pension benefits which are often prescribed by law. In the private sector, in contrast, pensions are typically a bargaining issue.

Additional sources of information

For a more detailed discussion on the series, see the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 10. Comprehensive data are published in press releases issued quarterly (in January, April, July, and October) for private industry, and semi-

annually (in February and August) for State and local government. Historical data and additional detailed tabulations for the prior calendar year appear in the April issue of the BLS monthly periodical, *Current Wage Developments*.

Work stoppages

Description of the series

Data on **work stoppages** measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of time lost because of stoppage.

Data are largely from newspaper accounts and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

Additional sources of information

Data for each calendar year are reported in a BLS press release issued in the first quarter of the following year. Monthly data appear in the BLS monthly periodical, *Current Wage Developments*. Historical data appear in the BLS *Handbook of Labor Statistics*.

Other compensation data

Other BLS data on pay and benefits, not included in the Current Labor Statistics section of the *Monthly Labor Review*, appear in and consist of the following:

Industry Wage Surveys provide data for specific occupations selected to represent an industry's wage structure and the types of activities performed by its workers. The Bureau collects information on weekly work schedules, shift operations and pay differentials, paid holiday and vacation practices, and information on incidence of health, insurance, and retirement plans. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Monthly Labor Review*.

Area Wage Surveys annually provide data for selected office, clerical, professional, technical, maintenance, toolroom, powerplant, material movement, and custodial occupations common to a wide variety of industries in the areas (labor markets) surveyed. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Review*.

The National Survey of Professional, Administrative, Technical, and Clerical Pay provides detailed information annually on salary levels and distributions for the types of jobs mentioned in the survey's title in private employment. Although the definitions of the jobs surveyed reflect the duties and responsibilities in private industry, they are designed to match specific pay grades of Federal white-collar employees under the General Schedule pay system. Accordingly, this survey provides the legally required information for comparing the pay of salaried employees in the Federal civil service with pay in private industry. (See Federal Pay Comparability Act of 1970, 5 U.S.C. 5305.) Data are published in a BLS news release issued in the summer and in a bulletin each fall; summaries and analytical articles also appear in the *Review*.

Employee Benefits Survey provides nationwide information on the incidence and characteristics of employee benefit plans in medium and large establishments in the United States, excluding Alaska and Hawaii. Data are published in an annual BLS news release and bulletin, as well as in special articles appearing in the *Review*.

PRICE DATA
(Tables 2; 30–41)

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI–W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all urban consumer index (CPI–U) introduced in 1978 is representative of the 1972–73 buying habits of about 80 percent of the noninstitutional population of the United States at that time, compared with 40 percent represented in the CPI–W. In addition to wage earners and clerical workers, the CPI–U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 24,000 retail establishments and 24,000 tenants in 85 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 28 major urban centers are presented in table 31. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI–U. A rental equivalence method replaced the

asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes.

Additional sources of information

For a discussion of the general method for computing the CPI, see *BLS Handbook of Methods, Volume II, The Consumer Price Index*, Bulletin 2134–2 (Bureau of Labor Statistics, 1984). The recent change in the measurement of homeownership costs is discussed in Robert Gillingham and Walter Lane, "Changing the treatment of shelter costs for homeowners in the CPI," *Monthly Labor Review*, June 1982, pp. 9–14.

Additional detailed CPI data and regular analyses of consumer price changes are provided in the *CPI Detailed Report*, a monthly publication of the Bureau. Historical data for the overall CPI and for selected groupings may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Producer Price Indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 60,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The stage of processing structure of Producer Price Indexes organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1976, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

Notes on the data

Beginning with the January 1986 issue, the *Review* is no longer presenting tables of Producer Price Indexes for commodity groupings, special composite groups, or SIC industries. However, these data will continue to be presented in the Bureau's monthly publication *Producer Price Indexes*.

The Bureau has completed the first major stage of its comprehensive overhaul of the theory, methods, and procedures used to construct the Producer Price Indexes. Changes include the replacement of judgment sampling with probability sampling techniques; expansion to systematic coverage of the net output of virtually all industries in the mining and manufacturing sectors; a shift from a commodity to an industry orientation; the exclusion of imports from, and the inclusion of exports in, the survey universe; and the respecification of commodities priced to conform to Bureau of the Census definitions. These and other changes have been phased in gradually since 1978. The result is a system of indexes that is easier to use in conjunction with data on wages, productivity, and employment and other series that are organized in terms of the Standard Industrial Classification and the Census product class designations.

Additional sources of information

For a discussion of the methodology for computing Producer Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 7.

Additional detailed data and analyses of price changes are provided monthly in *Producer Price Indexes*. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

International price indexes

Description of the series

The BLS **International Price Program** produces quarterly export and import price indexes for nonmilitary goods traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts: it includes corporations, businesses, and individuals but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents. With publication of an all-import index in February 1983 and an all-export index in February 1984, all U.S. merchandise imports and exports now are represented in these indexes. The reference period for the indexes is 1977 = 100, unless otherwise indicated.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected quarterly by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first 2 weeks of the third month of each calendar quarter—March, June, September, and December. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined by the 4- and 5-digit level of detail of the Standard Industrial Trade Classification System (SITC). The calculation of indexes by SITC category facilitates the comparison of U.S. price trends and sector production with similar data for other countries. Detailed indexes are also computed and published on a Standard Industrial Classification (SIC-based) basis, as well as by end-use class.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. Price relatives are assigned equal importance within each weight category and are then aggregated to the SITC level. The values assigned to each weight category are based on trade value figures compiled

by the Bureau of the Census. The trade weights currently used to compute both indexes relate to 1980.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's quarterly questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

For the export price indexes, the preferred pricing basis is f.a.s. (free alongside ship) U.S. port of exportation. When firms report export prices f.o.b. (free on board), production point information is collected which enables the Bureau to calculate a shipment cost to the port of exportation. An attempt is made to collect two prices for imports. The first is the import price f.o.b. at the foreign port of exportation, which is consistent with the basis for valuation of imports in the national accounts. The second is the import price c.i.f. (cost, insurance, and freight) at the U.S. port of importation, which also includes the other costs associated with bringing the product to the U.S. border. It does not, however, include duty charges.

Additional sources of information

For a discussion of the general method of computing International Price Indexes, see BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 8.

Additional detailed data and analyses of international price developments are presented in the Bureau's quarterly publication *U.S. Import and Export Price Indexes* and in occasional *Monthly Labor Review* articles prepared by BLS analysts. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

PRODUCTIVITY DATA
(Tables 2; 42–47)

U. S. productivity and related data

Description of the series

The productivity measures relate real physical output to real input. As such, they encompass a family of measures which include single factor input measures, such as output per unit of labor input (output per hour) or output per unit of capital input, as well as measures of multifactor productivity (output per unit of labor and capital inputs combined). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the value of goods and services in constant prices produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the value of goods and services in constant dollars produced per unit of capital services input.

Multifactor productivity is the ratio output per unit of labor and capital inputs combined. Changes in this measure reflect changes in a number of factors which affect the production process such as changes in technology, shifts in the composition of the labor force, changes in capacity utilization, research and development, skill and efforts of the work force, management, and so forth. Changes in the output per hour measures reflect the impact of these factors as well as the substitution of capital for labor.

Compensation per hour is the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, and the wages, salaries, and supplementary payments for the self-employed (except for nonfinancial corporations in which there are no self-employed)—the sum divided by hours paid for. **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current dollar value of output and dividing by output. **Unit nonlabor costs** contain all the components of unit nonlabor payments *except* unit profits.

Unit profits include corporate profits and the value of inventory adjustments per unit of output.

Hours of all persons are the total hours paid of payroll workers, self-employed persons, and unpaid family workers.

Capital services is the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Labor and capital inputs combined are derived by combining changes in labor and capital inputs with weights which represent each component's share of total output. The indexes for capital services and combined units of labor and capital are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Output measures for the business sector and the nonfarm businesss sector exclude the constant dollar value of owner-occupied housing, rest of world, households and institutions, and general government output from the constant dollar value of gross national product. The measures are derived from data supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are developed from data of the Bureau of Labor Statistics and the Bureau of Economic Analysis.

The productivity and associated cost measures in tables 42–44 describe the relationship between output in real terms and the labor time and capital services involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input. Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; capital investment; level of output; utilization of capacity, energy, and materials; the organization of production; managerial skill; and the characteristics and efforts of the work force.

Additional sources of information

Descriptions of methodology underlying the measurement of output per hour and multifactor productivity are found in the BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 13. Historical data for selected industries are provided in the Bureau's *Handbook of Labor Statistics*, 1985, Bulletin 2217.

International comparisons

Description of the series

Comparative measures of labor force, employment, and unemployment (tables 45 and 46) are prepared regularly for the United States, Canada, Australia, Japan, France, Germany, Great Britain, Italy, the Netherlands, and Sweden. Unemployment rates, approximating U.S. concepts, are prepared monthly for most of the countries; the other measures, annually.

The Bureau of Labor Statistics also prepares international comparisons of manufacturing labor productivity and labor costs (table 47) that cover the United States and 11 foreign countries—those listed above plus Belgium and Norway. These measures are limited to trend comparisons; that is, intercountry series of changes over time, rather than level comparisons because reliable international comparisons of the levels of manufacturing are unavailable. The U.S. measures are described in the notes on U.S. productivity measurement; the measures for foreign countries are compiled from various national and international data sources.

Definitions

Output measures are constant value output (value added) from the national accounts of each country, except for those for Japan prior to 1970 and for the Netherlands for 1969 forward, which are indexes of industrial production. The national accounting methods for measuring real output differ considerably among the 12 countries, but the use of different procedures does not, in itself, connote lack of comparability—rather, it reflects differences among countries in the availability and reliability of underlying data series.

Hours and compensation measures refer to all employed persons including the self-employed in the United States and Canada, and to all wage and salary employees in the other countries. *Hours* refer to hours *paid* in the United States, hours *worked* in the other countries. *Compensation (labor costs)* includes not only all payments made directly to employees and employer expenditures for social insurance and private benefit plans, but changes in significant employment or payroll taxes that are not compensation to employees but are labor costs to employers (France, Sweden, and the United Kingdom). Self-employed workers are included in the U.S. and Canadian figures by assuming that their hourly compensation is equal to the average for wage and salary employees.

Notes on the data

The data for the foreign countries in tables 45 and 46 have been adjusted, where necessary, for greater comparability with U.S. definitions of employment and unemployment. The adjusted statistics have been adapted to the age at which compulsory schooling ends in each country. Therefore, the adjusted statistics relate to the civilian population age 16 and over in the United States, France, and Sweden, and from 1973 forward, Great Britain; 15 and over in Canada, Australia, Japan, Germany, and the Netherlands; and 14 and over in Italy. Prior to 1973, the data for Great Britain related to persons age 15 and over. The institutional population is included in the denominator of the labor force participation rates and employment-population ratios for Japan and Germany.

For most of the countries in table 47, the measures refer to total manufacturing as defined by the International Standard Industrial Classification. However, the measures for France (beginning 1959), Italy (beginning 1970), and the United Kingdom (beginning 1976) refer to manufacturing and mining less energy-related products. For all countries, manufacturing includes the activities of government enterprises.

In addition, for all countries, preliminary estimates for recent years are generally based on current indicators of manufacturing output, employment and hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available.

Additional sources of information

For further information, see *International Comparisons of Unemployment*, Bulletin 1979 (Bureau of Labor Statistics, 1978), Appendix B and Supplements to Appendix B. Additional detail is also found in the BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 16. Additional international comparison statistics are available in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). The most recent statistics are presented and analyzed annually in the *Monthly Labor Review*, typically in the December issue (for the previous year) and in February.

OCCUPATIONAL INJURY AND ILLNESS DATA

(Table 48)

Description of the series

The Annual Survey of Occupational Injuries and Illnesses is designed to collect data on injuries and illnesses based on records which employers in the following industries maintain under the Occupational Safety and Health Act of 1970: agriculture, forestry, and fishing; oil and gas extraction; construction; manufacturing; transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. Excluded from the survey are self-employed individuals, farmers with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies.

Because the survey is a Federal–State cooperative program and the data must meet the needs of participating State agencies, an independent sample is selected for each State. The sample is selected to represent all private industries in the States and territories. The sample size for the survey is dependent upon (1) the characteristics for which estimates are needed; (2) the industries for which estimates are desired; (3) the characteristics of the population being sampled; (4) the target reliability of the estimates; and (5) the survey design employed.

While there are many characteristics upon which the sample design could be based, the total recorded case incidence rate is used because it is one of the most important characteristics and the least variable; therefore, it requires the smallest sample size.

The survey is based on stratified random sampling with a Neyman allocation and a ratio estimator. The characteristics used to stratify the establishments are the Standard Industrial Classification (SIC) code and size of employment.

Definitions

Recordable occupational injuries and illnesses are: (1) occupational deaths, regardless of the time between injury and death, or the length of the illness; or (2) nonfatal occupational illnesses; or (3) nonfatal occupational injuries which involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment (other than first aid).

Occupational injury is any injury such as a cut, fracture, sprain, amputation, and so forth, which results from a work accident or from exposure involving a single incident in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to environmental factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday cases are cases which involve days away from work, or days of restricted work activity, or both.

Lost workday cases involving restricted work activity are those cases which result in restricted work activity only.

Lost workdays away from work are the number of workdays (consecutive or not) on which the employee would have worked but could not because of occupational injury or illness.

Lost workdays—restricted work activity are the number of workdays (consecutive or not) on which, because of injury or illness: (1) the employee was assigned to another job on a temporary basis; or (2) the employee worked at a permanent job less than full time; or (3) the employee worked at a permanently assigned job but could not perform all duties normally connected with it.

The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked even though able to work.

Incidence rates represent the number of injuries and/or illnesses or lost workdays per 100 full-time workers.

Notes on the data

Estimates are made for industries and employment-size classes and for severity classification: fatalities, lost workday cases, and nonfatal cases without lost workdays. Lost workday cases are separated into those where the employee would have worked but could not and those in which work activity was restricted. Estimates of the number of cases and the number of days lost are made for both categories.

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses, or lost workdays, per 100 full-time employees. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Only a few of the available measures are included in the *Handbook of Labor Statistics*. Full detail is presented in the annual bulletin, *Occupational Injuries and Illnesses in the United States, by Industry*.

Comparable data for individual States are available from the BLS Office of Occupational Safety and Health Statistics.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration, respectively. Data from these organizations are included in BLS and State publications. Federal employee experience is compiled and published by the Occupational Safety and Health Administration. Data on State and local government employees are collected by about half of the States and territories; these data are not compiled nationally.

Additional sources of information

The Supplementary Data System provides detailed information describing various factors associated with work-related injuries and illnesses. These data are obtained from information reported by *employers* to State workers' compensation agencies. The Work Injury Report program examines selected types of accidents through an employee survey which focuses on the circumstances surrounding the injury. These data are not included in the *Handbook of Labor Statistics* but are available from the BLS Office of Occupational Safety and Health Statistics.

The definitions of occupational injuries and illnesses and lost workdays are from *Recordkeeping Requirements under the Occupational Safety and Health Act of 1970*. For additional data, see *Occupational Injuries and Illnesses in the United States, by Industry*, annual Bureau of Labor Statistics bulletin; BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 17; *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985), pp. 411–14; annual reports in the *Monthly Labor Review*; and annual U.S. Department of Labor press releases.

1. Labor market indicators

Selected indicators	1984	1985	1984		1985				1986	
			III	IV	I	II	III	IV	I	II

18. Indexes of diffusion: Industries in which employment increased, data seasonally adjusted

(In percent)

Time span and year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Over 1-month span												
1984	67.8	72.7	67.8	67.8	62.4	65.4	62.2	55.9	60.5	63.0	60.5	57.9
1985	52.4	47.8	53.8	49.2	51.6	47.0	58.2	58.8	60.8	61.9	57.8	59.5
1986	59.7	53.5	45.1	54.1	49.2	45.9	50.8	-	-	-	-	-
Over 3-month span												
1984	78.6	75.1	75.9	71.4	71.6	68.1	63.2	58.1	56.8	53.5	58.1	53.0
1985	51.1	49.7	46.2	46.2	45.1	51.4	49.7	51.1	55.1	56.9	61.4	60.5
1986	58.1	54.3	51.1	49.7	48.1	48.5	-	-	-	-	-	-
Over 6-month span												
1984	78.1	78.5	77.0	75.1	69.2	65.1	63.2	59.2	58.6	53.2	48.7	54.9
1985	49.2	47.8	43.0	45.9	44.3	44.3	48.9	50.8	54.1	57.0	57.0	55.9
1986	53.8	53.8	47.8	48.5	-	-	-	-	-	-	-	-
Over 12-month span												
1984	81.1	78.1	72.2	72.2	68.9	67.8	65.7	62.7	58.7	54.6	51.4	48.6
1985	46.2	45.7	46.8	43.6	44.9	47.3	47.8	48.9	47.3	49.5	48.9	49.5
1986	50.3	-	-	-	-	-	-	-	-	-	-	-

- Data not available.

NOTE: Figures are the percent of industries with employment rising. (Half of the unchanged components are counted as rising.) Data are centered within the spans. See the "Definitions" in this section. See "Notes on the data" for a description of the most recent benchmark revision.

19. Annual data: Employment status of the noninstitutional population

(Numbers in thousands)

Employment status	1977	1978	1979	1980	1981	1982	1983	1984	1985
Noninstitutional population	160,689	163,541	166,460	169,349	171,775	173,939	175,891	178,080	179,912
Labor force									
Total (number)	100,665	103,882	106,559	108,544	110,315	111,872	113,226	115,241	117,167

---

[1] Cost (cents-per-hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.

[2] Consist of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

[3] Consists of legislative, judicial, administrative, and regulatory activities.

[4] Includes, for example, library, social, and health services.

---

[1] The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the *Monthly Labor Review* Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.

25. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Quarterly average							
	1984	1985	1984		1985				1986	
			III	IV	I	II	III	IV	I	II^p
Specified adjustments:										
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:										
First year of contract	3.6	2.6	2.7	3.7	3.6	3.5	2.0	2.0	0.4	0.7
Annual rate over life of contract	2.8	2.7	3.1	2.0	2.7	3.4	3.0	1.4	1.3	1.6
Wage adjustments, settlements covering 1,000 workers or more:										
First year of contract	2.4	2.3	2.1	2.3	3.3	2.5	2.0	2.1	1.0	1.3
Annual rate over life of contract	2.4	2.7	2.6	1.5	3.2	2.8	3.1	1.9	1.6	2.0
Effective adjustments:										
Total effective wage adjustment [3]	3.7	3.3	1.2	.7	.7	.8	1.2	.5	.6	.7
From settlements reached in period	.8	.7	.2	.3	.1	.2	.2	.1	.0	.2
Deferred from settlements reached in earlier periods	2.0	1.8	.7	.2	.6	.5	.5	.2	.4	.6
From cost-of-living-adjustments clauses	.9	.7	.3	.2	.1	.1	.4	.1	.2	.0

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

p = preliminary.

26. Average specified compensation and wage adjustments, major collective bargaining settlements in private industry situations covering 1,000 workers or more during 4-quarter periods (in percent)

Measure	Average for four quarters ending–							
	1984		1985				1986	
	III	IV	I	II	III	IV	I	II^p
Specified total compensation adjustments, settlements covering 5,000 workers or more, all industries:								
First year of contract	4.2	3.6	3.4	3.4	3.1	2.6	2.3	1.5
Annual rate over life of contract	3.2	2.8	2.6	2.7	2.7	2.7	2.6	2.0
Specified wage adjustments, settlements covering 1,000 workers or more:								
All industries								
First year of contract	3.2	2.4	2.4	2.4	2.4	2.3	2.0	1.7

[1] Data do not meet publication standards.

p = preliminary.

27. Average effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more during 4-quarter periods (in percent)

Effective wage adjustment	Average for four quarters ending–						
	1984	1985				1986	
	IV	I	II	III	IV	I	II[p]
For all workers:[1]							
Total	3.7	3.6	3.5	3.5	3.3	3.1	2.9
From settlements reached in period	.8	.7	.9	.9	.7	.6	.5
Deferred from settlements reached in earlier period	2.0	2.2	1.9	1.8	1.8	1.7	1.6
From cost-of-living-adjustments clauses	.9	.7	.7	.8	.7	.8	.7
For workers receiving changes:							
Total	4.4	4.5	4.2	4.3	4.1	4.0	3.8
From settlements reached in period	3.0	2.9	2.9	2.8	3.4	2.9	2.5
Deferred from settlements reached in earlier period	4.0	4.2	3.9	3.7	3.7	3.5	3.4
From cost-of-living-adjustments clauses	2.7	2.3	2.3	2.8	2.2	2.5	2.1

[1] Because of rounding total may not equal sum of parts.

[p] = preliminary.

28. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, State and local government collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Second 6 months 1985[p]
	1984	1985	
Specified adjustments:			
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:			
First year of contract	5.2	4.2	3.8
Annual rate over life of contract	5.4	5.1	5.3
Wage adjustments, settlements covering 1,000 workers or more:			
First year of contract	4.8	4.6	4.4
Annual rate over life of contract	5.1	5.4	5.6
Effective adjustments:			
Total effective wage adjustment [3]	5.0	5.7	4.1
From settlements reached in period	1.9	4.1	3.2
Deferred from settlements reached in earlier periods	3.1	1.6	.9
From cost-of-living-adjustment clauses	([4])	([4])	([4])

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

[4] Less than 0.05 percent.

[p] = preliminary.

29. Work stoppages involving 1,000 workers or more

Measure	Annual totals		1985						1986						
	1984	1985	July	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.[p]	Feb.[p]	Mar.[p]	Apr.[p]	May[p]	June[p]	July
Number of stoppages:															
Beginning in period	62	54	9	6	11	6	3	2	4	3	3	4	6	11	
In effect during period	68	61	13	18	20	20	13	9	7	7	9	9	11	16	
Workers involved:															
Beginning in period (in thousands)	376.0	323.9	50.1	15.3	69.5	76.6	26.2	8.2	7.6	24.0	12.3	7.2	29.7	199.1	
In effect during period (in thousands)	391.0	584.1	56.9	88.8	93.9	119.3	47.0	38.0	12.0	29.4	39.7	18.7	42.3	207.0	
Days idle:															
Number (in thousands)	8,499.0	7,079.0	476.5	810.6	883.8	1,426.8	666.2	661.9	170.0	309.5	390.6	321.5	314.6	3,707.4	
Percent of estimated working time[1]	.04	.03	.02	.04	.04	.06	.04	.03	.01	.02	.02	.02	.02	.07	

[1] Agricultural and government employees are included in the total employed and total working time: private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in "'Total economy' measure of strike idleness," *Monthly Labor Review, Octobe*

1968, pp. 54-56.

[1] Area is generally the Standard Metropolitan Statistical Area (SMSA), exclusive of farms. L.A.-Long Beach, Anaheim, Calif. is a combination of two SMSA's, and N.Y., N.Y.-Northeastern N.J. and Chicago, Ill.-Northwestern Ind. are the more extensive Standard Consolidated Areas. Area definitions are those established by the Office of Management and Budget in 1973, except for Denver-Boulder, Colo. which does not include Douglas County. Definitions do not include revisions made since 1973.

[2] Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:

M - Every month.
1 - January, March, May, July, September, and November.
2 - February, April, June, August, October, and December.

[3] Regions are defined as the four Census regions.

The population size classes are aggregations of areas which have urban population as defined:

A-1 - More than 4,000,000.
A-2 - 1,250,000 to 4,000,000.
B - 385,000 to 1,250,000
C - 75,000 to 385,000.
D - Less than 75,000.

Population size class A is the aggregation of population size classes A-1 and A-2.

- Data not available.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Because each Local index is a small subset of the national index, it has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error than the national index. As a result, local area indexes show greater volatility than the national index, although their long-term trends are quite similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in escalator clauses.

France	9.9	10.4	10.3	10.5	10.4	10.4	10.1	10.3	10.5
Germany	7.8	7.9	7.8	7.9	8.0	7.9	7.8	7.8	7.6
Great Britain	12.9	13.2	13.0	13.1	13.2	13.4	13.0	13.1	13.3
Italy	5.9	6.0	5.8	5.9	5.8	6.0	6.3	6.3	6.5
Sweden	3.1	2.8	3.0	3.0	2.9	2.8	2.7	2.8	2.6

[1] Quarterly rates are for the first month of the quarter.

[2] Major changes in the Italian labor force survey, introduced in 1977, resulted in a large increase in persons enumerated as unemployed. However, many persons reported that they had not actively sought work in the past 30 days, and they have been provisionally excluded for comparability with U.S. concepts. Inclusion of such persons would more than double the Italian unemployment rate shown.

– Data not available.

NOTE: Quarterly figures for France, Germany, and Great Britian are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures.

46. Annual data: Employment status of the civilian working-age population, ten countries

---

[1] Total cases include fatalities.

[2] The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as:
(N/EH) X 200,000, where:
N = number of injuries and illnesses or lost workdays.
EH = total hours worked by all employees during calendar year.
200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year.)

[3] Excludes farms with fewer than 11 employees since 1976.

Labor Month In Review

TRANSITION. The Institute for Contemporary Studies published an evaluation of the role of unions in the 100th year after the founding of the American Federation of Labor. The book, *Unions in Transition* (ICS Press, 506 pages, $29.95), edited by Seymour Martin Lipset of the Hoover Institution, Stanford University, includes contributions from more than a dozen academic observers and labor practitioners. Some excerpts:

Walter Galenson, Cornell University: American unions have survived and prospered because they . . . were flexible enough to alter their strategies to meet the demands of the time. The present soul-searching that is going on within the labor movement suggests that some new approaches may emerge, particularly if unions are to move beyond the bounds of their present sectoral confines.

Leo Troy, Rutgers University: As the American labor movement begins its second century, it apparently has entered a new stage in its history, a stage of permanent decline. Organized labor has lost millions of members since its peak in 1975, while its grip on the labor market has dropped to the levels of the Great Depression. The market seems to have rejected unions in the large sectors of the private economy and in growth areas of the country.

Ray Marshall, University of Texas: Most economic and technological trends are against unions as traditionally organized. The unions will therefore need to develop new procedures to deal with the internationalized information world. Because of the importance of collective bargaining and free labor movements for the Nation's economic, political, and social health, it is in the public interest to encourage these adjustments and strengthen the workers' right to decide for themselves whether or not they want to be represented by unions.

Richard B. Freeman, Harvard University: In the world of perfect full employment and competitive markets, unions would be unnecessary. In the real world in which we live unions can and generally do perform valuable economic functions. An economy is likely to operate efficiently when there is a sufficient number of union and of nonunion firms to offer alternative work environments to workers, innovation in workplace rules and conditions, and competition in the market.

Seymour Lipset, Stanford University: Most Americans who are normally sympathetic to the needs of the weak and the underprivileged do not classify labor organizations among the oppressed. Rather, like big business, they are seen as powerful and essentially self-serving. But corporations have an advantage in that the public also thinks they inherently contribute to the community in the form of jobs, goods, and services. Unions are perceived as worse than business in two respects; first, they are viewed as giving low priority to the public interest and as working against the good of the whole society, and second, their leaders are believed to be exceptionally corrupt and unethical. In short, the principal virtue of unions is that they serve the interest of their members. Their principal defect is that, by doing exactly that, unions seem to do little to benefit the public interest.

Lane Kirkland, AFL-CIO: Any analysis of the state of American unions, especially one pointing to or predicting their decline, should include the following disclaimer in the interest of accuracy: It has all been said before.

Labor's obituary has been written at least once in every one of the 105 years of our existence, and nearly that many causes of death have been diagnosed. Some of our most prominent labor journalists have earned their keep by writing of our demise each Labor Day, just as some of our better-known labor economists and academics have earned tenure by publishing predictions that unions would perish. It seems we must be forever perishing so that others may be forever publishing.

Alexander Trowbridge, National Association of Manufacturers: Labor and management are at the crossroads in collective bargaining. Certainly, the growth of participative management mechanisms, gainsharing, employment security, and employee identification with productivity and profits of a company justify some optimism that both labor and management have seen the realities of global competition and its impact, as well as the responses that are necessary to successfully face this competition. □

A half-year pause in inflation: its antecedents and structure

The Consumer Price Index was almost unchanged during the first half, suggesting that 1986 will show the lowest inflation rate in 20 years; plunging energy prices offset strong increases for some services

John F. Early, Walter Lane, and Philip Sturm

Inflation as measured by the Consumer Price Index for all Urban Consumers (CPI-U) declined at a seasonally adjusted annual rate of 0.2 percent during the first 6 months of 1986. While a continuation of this pattern is unlikely throughout the remainder of the year, the resulting change for 1986 will probably be the smallest annual increase since the first half of the 1960's.[1]

The first-half decline reflected the sharp drop in crude oil prices, as the index for energy commodities—fuel oil, coal, bottled gas, and motor fuels fell at an annual rate of 40.2 percent in the first half of 1986. Prices for used cars and grocery store foods also declined in the first half. On the other hand, shelter costs continued to advance at an annual rate of about 5 percent. The index for all items excluding food, shelter, energy, and used cars increased at an annual rate of 4 percent during the first 6 months. Within this group, however, price movements for commodities and for services continued to diverge. Price increases in the goods sector moderated further, but prices for services, in particular medical care, accelerated. (See table 1.)

Background 1960 to 1981

The early 1960's were characterized by rapid economic expansion, with prices increasing at an annual rate of 1.3 percent for the 5-year period which ended in December 1965. (See chart 1.) Price pressures developed in the late 1960's, however, as expenditures for the Vietnam War stimulated an economy already at nearly full employment. The rate of inflation in consumer prices rose from less than 2 percent in 1965 to more than 6 percent in 1969.

From chart 2, one can identify the general composition of price change in each of these periods. The top line displays the average annual rate of change for the all-items CPI-U during the periods identified on the horizontal axis. This seasonally adjusted overall inflation rate can be constructed as the sum of the individual contributions of four major classes of consumer expenditures—energy, food, shelter, and all other—as follows:

Period	All items	Effect on all items: Energy	Food	Shelter	Other
Dec. 1960–Dec. 1965	1.3	.023	.406	.245	.626

John F. Early is Assistant Commissioner for Consumer Prices and Price Indexes, Bureau of Labor Statistics. Walter Lane and Philip Sturm are economists in that office.

From the chart, one can see that the acceleration in prices from the first half to the second half of the 1960's was widespread, except that energy prices had very little impact.

The recession which began late in 1969 caused the rate of price increase to subside only partially, and much of that reduction was due to the effect of declining mortgage interest rates on the shelter component of the CPI. In reaction to the failure of inflation to abate swiftly and fully, President Nixon announced a wage and price freeze on August 15, 1971. The initial price freeze and subsequent Phase II economic controls were accompanied by a lower rate of inflation during the final months of 1971 and throughout 1972. Prices, however, started to rise more quickly in 1973, and further inflation followed with the relaxation of controls in August and the oil embargo in October. Although the direct effects of the oil embargo on inflation were substantial, they were far from unique. Sharply higher mortgage interest rates and house prices drove up shelter costs; food prices, influenced in part by worldwide commodity inflation, rose rapidly; and prices for most other goods and services began to accelerate.

Inflation climbed to double-digit rates during 1974 and registered what was then the largest calendar year change in the history of the CPI, except for the inflationary periods directly associated with the two World Wars. With the steep recession of 1973–75, inflation moderated substantially so that, by the end of 1976, consumer prices were rising at an annual rate of less than 5 percent. With the economic expansion in 1977, prices began to accelerate. Then sharp increases in energy prices were fueled by events associated with the Iranian crisis, and rapid price rises for food and shelter costs followed, pushing consumer price rises to unprecedented peacetime rates during 1979, 1980, and, indeed, for most of 1981.

Table 1. Annual percent changes for selected groupings of consumer prices, 1982–86

Item	12 months ended December—				6 months ended June—
	1982	1983	1984	1985	1986[1]
All items	3.9	3.8	4.0	3.8	−0.2

Chart 1. Consumer Price Index for All Urban Consumers, 12-month percent changes, 1960–1986

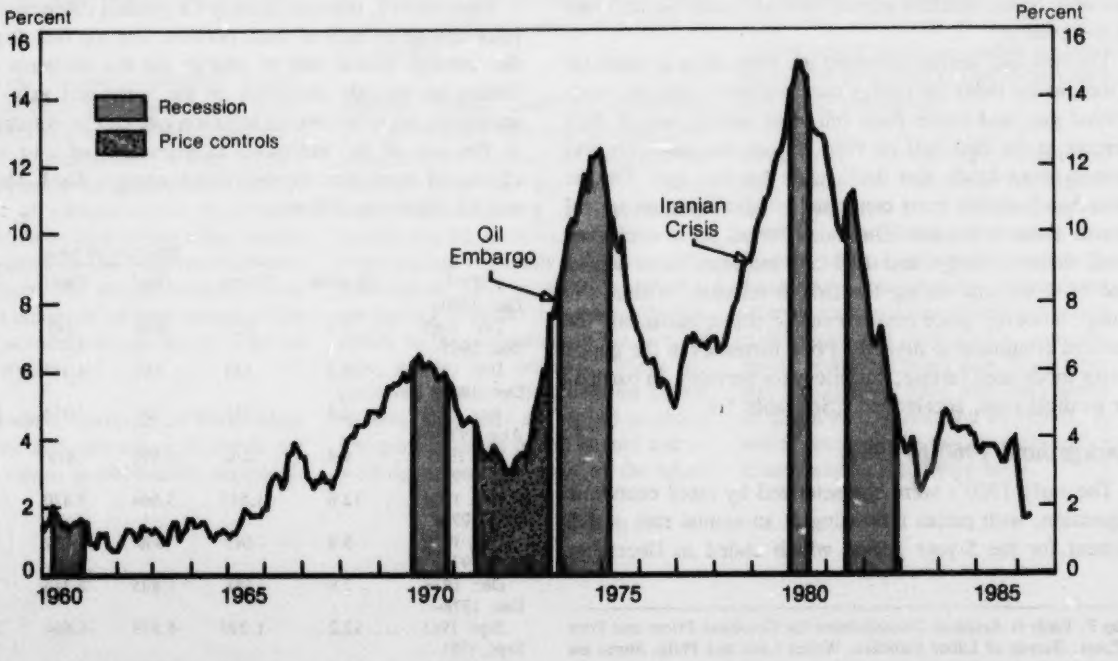

Chart 2. CPI average annual rate of change for selected periods by the effects of major components, December 1960 to June 1986

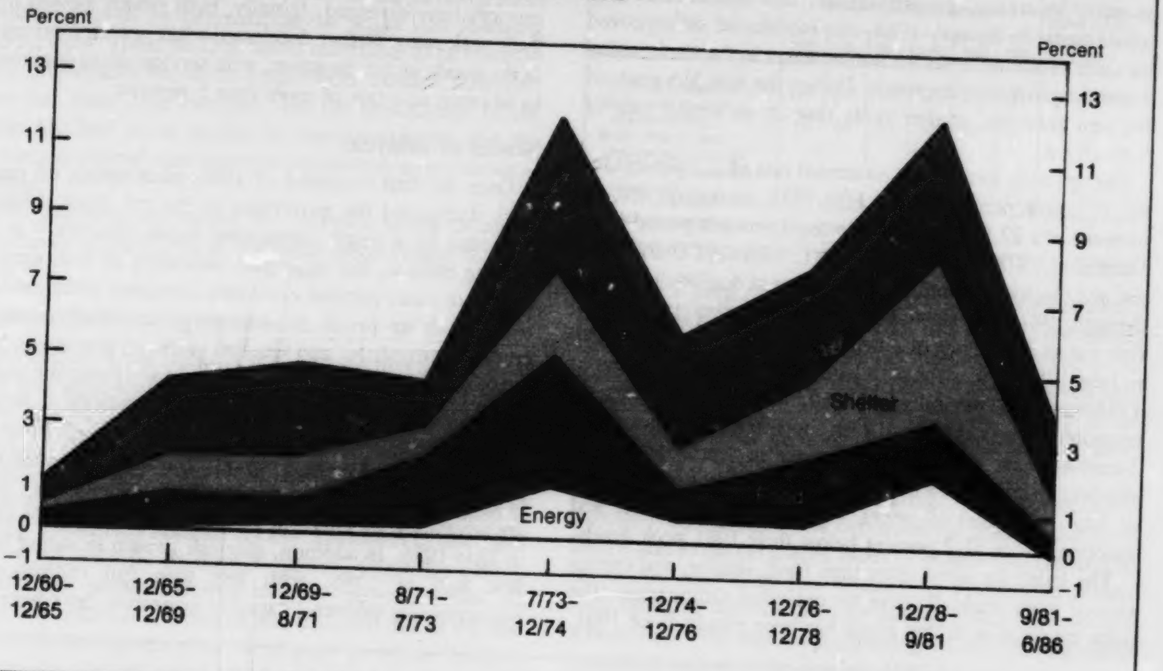


Deceleration since 1981

Two back-to-back recessions (1980 and 1981–82), a tight monetary policy, and lessened control by OPEC of world petroleum supplies all contributed to a rapid reduction in the rate of inflation beginning in the fourth quarter of 1981. This moderation in prices brought an end to the "ratchet phenomenon" that had characterized inflation since 1960. Before 1981, each succeeding low point in inflation was higher than the preceding low, and each high point was also higher than the preceding high. (See chart 1.) The 3.9-percent price increase for 1982 was the smallest annual increase in 10 years.

The price deceleration that occurred in the 57 months through June 1986 was particularly apparent in the energy, shelter, and food components of the CPI. (See charts 2 and 3.) Advances in these items had, of course, been responsible for much of the increase in the CPI in the past decade. Unlike earlier episodes, however, the index excluding the energy, shelter, and food components also moderated substantially, rising at a 4.8-percent seasonally adjusted annual rate during the 57 months through June 1986, compared with a 9.6-percent increase for the 12 months ended in September 1981. Chart 3 provides more detail than chart 2 on the post-1981 period. The data are as follows:

Period	All items	*Effect on all items*				
		Energy	*Food*	*Shelter*	*Other commodities*	*Other services*
Sept. 1981–Dec. 1982	4.0	.372	.488	.724	1.057	1.359
Dec. 1982–Dec. 1984	3.9	−.015	.606	1.071	1.059	1.179
Dec. 1984–Sept. 1985	3.2	.143	.296	1.284	.464	1.013
Sept. 1985–Dec. 1985	5.3	.402	1.022	1.405	1.103	1.368
Dec. 1985–June 1986	−.2	−2.580	.169	.971	.019	1.221

The slowdown in food prices preceded the deceleration in the overall CPI. For the 12-month period ended in September 1981, grocery store food prices had increased 5.5 percent, a rate half that of the overall index. Increases in each of the following 4 years were also less than those for the overall index. For the September 1981 to June 1986 period, grocery store food prices advanced at an average annual rate of 2.1 percent and the overall food component at a 2.8-percent rate.

The shelter component registered steep advances throughout most of the period from 1978 through September 1981. The rate of increase fell off sharply beginning in the fourth quarter of 1981, principally due to the behavior of house prices and mortgage interest rates, and advanced at an annual rate of 2.2 percent from September 1981 through

December 1982. Until January 1983, the CPI used an asset approach to measure shelter costs of homeowners. The asset treatment covered house prices, mortgage interest rates, property insurance, property taxes, and maintenance and repair costs. In January 1983, BLS introduced an improved measure of shelter costs for homeowners in the CPI-U, using a rental equivalence approach. During the first 3½ years of the new measure, shelter costs rose at an annual rate of 5.3 percent.

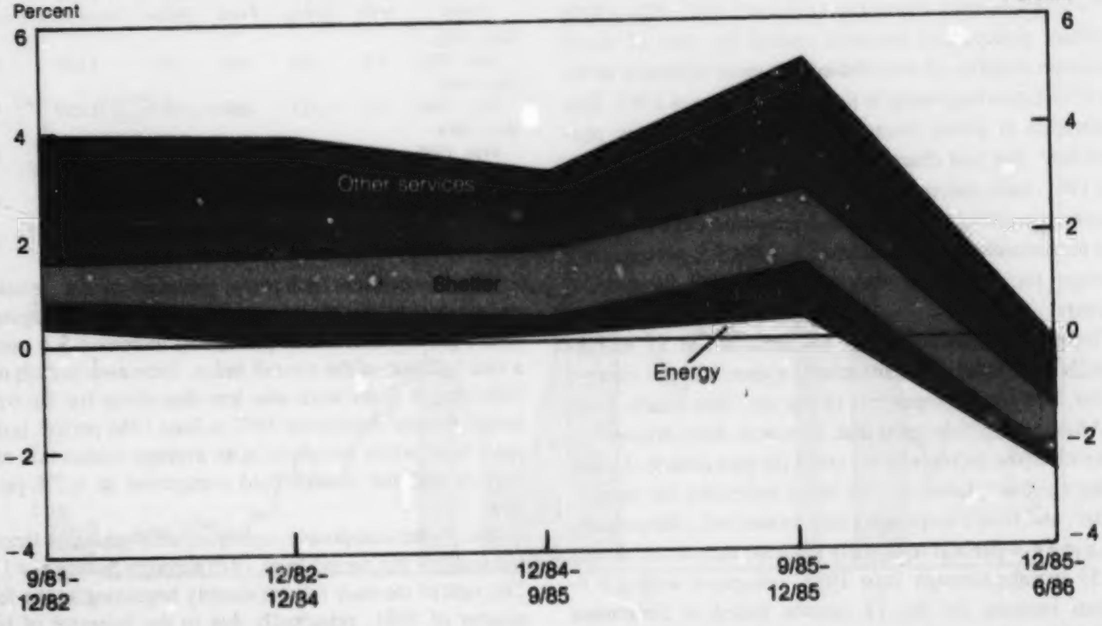
Energy costs declined at an annual rate of 2.1 percent for the 57-month period through June 1986, compared with an increase at a 22.9-percent rate in the 33-month period from December 1978 to September 1981. Although charges for gas and electricity continued to increase at double-digit rates through 1982, they slowed considerably beginning in 1983, rising at an annual rate of 2.6 percent in the 42 months ended in June 1986. Prices for petroleum products peaked in early 1981 and then generally declined, with the exception of temporary spurts associated with short-term shortages and a 5-cent-a-gallon gasoline tax increase in April 1983. The sharpest drop occurred during the first 6 months of 1986. As of June 1986, fuel oil prices were 35.2 percent lower and gasoline prices 31.2 percent below their 1981 peak levels.

The index for items other than food, shelter, and energy slowed more gradually than the excluded components. The price moderation in this group has been steady since 1981, when these prices rose, on average, by 9.4 percent. They increased less each year than in the preceding one, and by the end of 1985 the annual change was 3.7 percent. Within the group, however, price movements for commodities and services have diverged. Initially, both groups slowed from their peak rates; further deceleration has occurred primarily in the goods sector, however, with service prices continuing to advance at a rate of more than 5 percent.

Status at midyear

Over the first 6 months of 1986, plummeting oil prices have dominated the movement of the CPI. Such dramatic influence by a single component seems less likely in the coming months, but aggregate indicators of both material and labor costs portend continued consumer price moderation. Producer prices for nonenergy commodities at the crude, intermediate, and finished stages of processing have either declined or increased very moderately over the past 12 months. Measures of labor costs also indicate a lack of current pressure on prices. The Employment Cost Index has decelerated steadily since peaking at near double-digit rates in 1980, with total compensation for private industry workers advancing by only 3.8 percent in the 12 months ended in June 1986. In addition, sluggish growth in output in the first half of 1986, with less than full utilization of resources—at midyear, capacity utilization rates were less

Chart 3. CPI average annual rate of change for recent periods by the effects of major components, September 1981 to June 1986



than 79 percent and unemployment stood just under 7 percent—would appear to preclude any immediate cost pressures.

However, policymakers have taken measures designed to stimulate growth by depreciating the dollar and lowering interest rates. These policies could contribute to an increase in the CPI inflation rate in the longer term. To date, however, there has been little evidence that the devaluation of the dollar has had much impact on consumer prices and the declines in interest rates have not yet sparked an acceleration in output.

The following discussion is a detailed sector-by-sector assessment of the status of consumer price change in mid-1986.

The plunge in energy prices

The decline in the overall CPI during the first 6 months of 1986 was attributable to the sharp drop in energy prices—down 24.1 percent at an annual rate. (See chart 3.) The CPI excluding energy, during this period, advanced at a 3.1-percent annual rate. Prices for commodities and services within energy as well as within the overall CPI, continued to diverge. Principally because of OPEC's decision in late 1985 to abandon formally production quotas, prices for energy commodities plunged downward as contracted crude oil prices fell from $28 a barrel to less than half that at the end of June. Reflecting this drop, retail gasoline prices fell 22.3 percent and fuel oil prices, 27.6 percent, from December 1985 to June. From 1967 to the spring of 1981, prices for energy commodities rose about 80 percent faster than prices for nonenergy consumer items. As a result, the prices of energy commodities relative to the prices (on average) of nonenergy items were nearly 80 percent greater in early 1981 than in 1967, the base year for the CPI. By June of 1986, however, energy CPI commodity prices had fallen from their peaks and the prices for energy commodities stood in the same relationship to prices for nonenergy items as they had in 1967. (See chart 4.)

The index for energy services—natural gas and electricity—registered a moderate increase during the first 6 months of 1986. Charges for electricity rose at an annual rate of 4.8 percent and those for natural gas increased at a 1.6-percent annual rate. From 1967, the prices for energy services relative to those for nonenergy items rose somewhat more than half as fast as relative prices for energy commodities, peaking in mid-1983. Since then, charges for energy services have eased slightly, and by June 1986 they were in the same proportion to nonenergy prices as they had been in the spring of 1982.

Continuing rise in shelter costs

The movements in the CPI for shelter during the last 5 or 6 years are, on the surface, somewhat puzzling. As already noted, shelter costs were a major cause for the double-digit inflation during 1979, 1980, and first part of 1981. After rising 15.1 percent during 1980, the CPI for shelter rose a mere 2.4 percent in 1982. During this period, the shelter index was a major factor in the slowdown of the overall CPI. But since 1982 the shelter index has seemingly moved contrary to other prices—more than doubling its rate of increase, while other portions of the CPI continued to slow. (See table 2.)

Table 2. Annual changes in consumer prices for shelter, 1980–86

Item	12 months ended December—						6 months ended June—
	1980	1981	1982	1983	1984	1985	1986[1]
Official CPI for shelter	15.1	9.9	2.4	4.7	5.2	6.0	5.1
Shelter index on rental equivalence basis	9.0	8.8	6.2	4.7	5.2	6.0	5.1
Shelter index on rental equivalence basis, with estimated adjustment for vacant units	10.0	9.5	6.5	5.3	6.0	6.0	5.1

[1] Seasonally adjusted annual rate of change.

One can understand this unusual performance only through a careful review of two technical changes that have been made to the CPI shelter index. The first was the shift to an owners' equivalent rent measure for homeowner shelter costs effective with the CPI-U for January 1983.[2] The second was an improved method for treating vacant housing units, beginning with data for January 1985.[3]

The introduction of these two improvements affected both the shelter component and the All Items CPI. Consequently, it is advantageous for purposes of analyzing the trends in shelter costs to estimate these effects and adjust for them. The first line of data in table 2 contains annual inflation rates for the official CPI for shelter. It exhibits the unusual behavior noted above.

BLS has previously constructed and published enhanced experimental indexes which provide estimates of what the CPI would have been in years prior to 1983 if the owners' equivalent rent measure had been used.[4] The shelter component based on these rental equivalence estimates is contained in the second line of table 2. The owners' equivalent rent method produces indexes which reflect the change in shelter costs for homeowners. The previous method had included investment costs associated with purchasing a housing asset—costs that were inappropriate for the CPI. The differences between these two measures illustrate the problem. (See table 2.) The skyrocketing mortgage interest rates in early 1980 caused the official shelter index to rise 15.1 percent, two-thirds again as much as the actual shelter service cost rise measured using the more appropriate owners' equivalent rent measure. Similarly, when mortgage interest rates dropped sharply in 1982, the official shelter index rose less than half as much as the measure based on owners' equivalent rent.

The effects of the improved methods for treating vacant housing units in the CPI are a good deal less dramatic than those from the introduction of owners' equivalent rent. The final line of table 2 provides an analytical reconstruction of the shelter index as it would have looked had both owners' equivalent rent and the enhanced vacant unit procedure been used.

By adjusting the shelter index for the two methodological changes, it becomes easier to identify and explain the trends of shelter costs in the last few years. Like the CPI as a whole, shelter cost increases (on the reconstructed basis) began slowing in 1981. They continued to slow through 1983, then moved up slightly to a 6.0-percent annual rate in both 1984 and 1985. The first half of 1986 gives some indication of a further slowdown. Although the rise in shelter costs has clearly slowed, both the degree and speed of that adjustment have been considerably less than in the overall CPI. There are a number of institutional factors that contribute to the relatively slower adjustment of shelter costs—the almost universal use of leases that hold rent constant for extended periods, rent control in some local areas, and existing stable tenant-landlord relationships that make both reluctant to change terms too rapidly. In addition, the available stock of housing cannot adjust as quickly to changing demand conditions as can the supplies of most other consumer items.[5]

These institutional expectations are borne out historically. A long historical series is not available for the shelter CPI based on owners' equivalent rent, but the use of the residential rent CPI provides a reasonable proxy for the timing of changes in shelter costs in earlier years.[6] If we compare the points in time at which the residential rent CPI has reached its highest (peak) values and lowest (trough) values with the corresponding times for the All Items CPI, it is clear that the rate of rent increase almost always slows or accelerates well after the corresponding change occurs in the All Items CPI. (See table 3.) If the current episode of slowing inflation is consistent with earlier ones, one should not be too surprised if there were some additional modest slowing in shelter costs.[7]

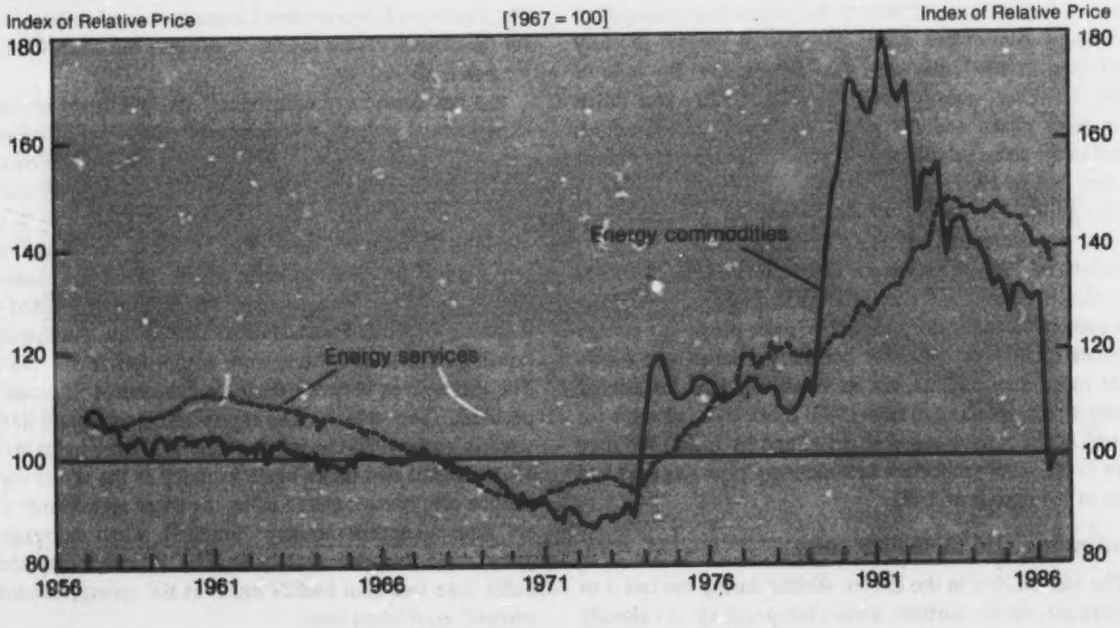
Table 3. Dates and timing of peak and trough rate for 12-month percent changes of consumer prices, 1947–80

All items		Residential rent		Months by which rent lags (leads) all items[1]	
Peak	Trough	Peak	Trough	Peak	Trough
March 1947	August 1949	June 1948	January 1951	15	17
February 1951	October 1954	October 1953	September 1955	30	11
April 1957	April 1959	December 1956	September 1964	– 4	65
February 1970	June 1972	April 1971	June 1972	14	0
December 1974	December 1976	(2)	(2)	–	–
March 1980	—	July 1980	—	4	–

[1] Positive numbers are lags—number of months after all items change. Negative numbers are leads—numbers of months before all items.

[2] Skipped cycle. Rate did not slow for any significant period of time.

Chart 4. Index of relative consumer prices of energy commodities and energy services, seasonally adjusted, 1957–1986



The trend in food prices

For the 6 months ended in June, the food index advanced at an annual rate of 1 percent with an increase in the cost of food away from home—up 4.1 percent at an annual rate—more than offsetting a decline in grocery store food prices—down 0.5 percent at an annual rate. Decreases in prices for beef and fruits and vegetables were responsible for the drop in the food-at-home component. Beef prices fell at an annual rate of 12.1 percent in the first 6 months. The drop in herd size, which has shrunk to its lowest levels in two decades, has not yet placed significant upward pressure on prices. Potential supplies were augmented when the U.S. Department of Agriculture (USDA) announced a large dairy cow buy-out program in late March. Nevertheless, in June, beef prices registered their first increase this year. Pork prices have already started upwards, as hog producers have begun to withhold breeding stock to rebuild their herds. As of June, the USDA estimated that pork cold storage supplies were 36 percent below their year-earlier levels. Poultry prices also advanced in the second quarter, partly due to increased demand and partly due to the impact on supplies of the adverse weather in the southeastern United States.

The decline in fruit and vegetable prices in the first half of 1986, however, is likely to continue. These prices, which rose sharply in response to adverse weather at the end of 1985, retreated and growing conditions generally were good in the first half of 1986. The severe drought in the Southeast should have only a limited effect on these prices because production is concentrated in other areas, which were not adversely affected by the weather conditions.

Other grocery store foods registered generally moderate increases during the first 6 months of the year. An exception was the index for nonalcoholic beverages, which advanced at double-digit rates, as coffee prices soared in the first quarter of 1986, before turning downward in the second quarter. This increase reflected the impact of the Brazilian drought in late 1985, which damaged the coffee bean crop.

Services except shelter and energy

As noted, price increases for services other than energy and shelter have, on average, slowed down significantly since 1981, but they remain substantially greater than the increases for nonenergy commodities.[8] This section will explore the structure and possible causes of the more limited deceleration response of service prices. In an effort to systematize this investigation, all consumer services besides shelter and energy have been classified into one of four groups: (1) those which have contributed to the overall slowing of prices and generally continue to demonstrate only modest price rises; (2) those for which prices have clearly slowed, but continue to rise a good deal faster than other prices; (3) those which provide continuing or growing upward pressure on inflation; and (4) those that defy classification even by these rather general categories. The results of this classification are displayed in table 4.

Price changes for a large number of services have slowed substantially since 1981. Perhaps most dramatic has been the sharp drop in finance charges for automobiles as interest rates generally have declined and automobile manufacturers have made extensive use of "below market rate" financing to stimulate car sales. Increases in airline fares have also fallen off markedly as declining fuel costs and fierce competition from both existing and newly formed airlines have driven fares down to very low levels on many of the more competitive routes. Another transportation service, namely taxis, has also had much slower fare growth, in part due to lower fuel costs and in part due to increased competition from improved availability of mass transit in some areas.

The AT&T divestiture, combined with competition from new long distance telephone carriers, has led to a number of substantial reductions in interstate long distance tolls. Although postage rates rose 10.2 percent in 1985, that was the only increase in more than 3 years, with the result that postage also contributed to the overall price slowdown.

The remaining services which have shown clear reductions in their inflation rates to levels of about 4 percent or less include appliance and furniture repair, apparel services, automobile maintenance and repair, personal care services (beauty and barber shops), and moving, storage, freight, household laundry, and drycleaning. (The 1985 increase in, moving costs may be related in part to the strengthening of the housing market and the associated demand for moving services.) These service establishments have benefited from moderation or declines in heating, transportation fuel, and supply costs. They also have a high proportion of relatively small establishments and fair amounts of local competition. Auto repair services may also be facing reduced demand because of the longer intervals between required maintenances on newer models.

Medical charges continue substantial rises

Other services have also experienced slowing price rises, but they continue to post substantial or even reaccelerating price increases. Medical care services are perhaps the most notable in that respect. Costs of professional medical services (physicians, dentists, optometrists, and so on) rose at double-digit rates during most of the 1979–81 period and slowed during 1982 and 1983 to annual rates of increase of between 7 and 8 percent. Beginning with 1984, charges for professional medical services have risen at a fairly constant rate of a bit over 6 percent. In addition to general reductions in inflation pressures on cost, factors which may have contributed to the slowing of professional medical service charges include (1) a voluntary 1-year freeze on physician fees urged by the American Medical Association (AMA) in February 1984; (2) declines in prices for precious metals used in dental fillings; (3) increased competition from advertising among dentists; and (4) modest increases in wages and benefits for employees in health industries—up 4.1 percent for the 12 months ended June 1986, about the same as for all civilian workers.[9]

Despite these factors, however, charges for services by medical professionals have stubbornly grown at annual rates in excess of 6 percent. One factor which may have contributed to this continued inflation is the widely publicized substantial increases in malpractice insurance premiums. These increases have tapered off, but continue to be quite high. After jumping more than 40 percent in 1982, average premium increases by 1984 were down to a smaller but still substantial 18.3 percent.[10] It is also possible that the measured CPI increases reflect more than pure price change. New diagnostic and treatment methods, procedures, and equipment may increase the costs of professional services. At the same time, however, they may improve the efficiency and efficacy of a diagnosis or treatment. To the extent that the higher charges are the result of better medical care, the increases are not pure price increases and should, in principle, not be included in the CPI. We do not know whether such quality increases are in fact contributing to the continued substantial rises in the medical care CPI, but it is a possibility that must be kept in mind.

Charges for hospital rooms and for other hospital and medical care services both rose at very high double-digit rates through 1982. Like many large service organizations, hospitals tend to be slow to adjust their fee schedules to reflect changes in their costs. As a result, slower price increases for hospitals came later than for many other segments of the economy—including those by medical professionals. Nevertheless, from 1983 through 1985, hospital fees slowed down quite significantly. Like the professional services component of the CPI, hospital costs have benefited from modest rises in compensation costs for employees. In addition, hospitals have come under increasing regulatory scrutiny by Federal, State and local government units in an effort to contain cost increases. In October 1983, the Federal Government imposed a Diagnostic Related Groups (DRG) fee structure on hospitals being reimbursed for Medicare-financed treatment. Under this process, a set fee is established for a specific class of treatment irrespective of the duration or specific procedures followed in a particular case. The objective is to encourage providers to identify and use the most cost-effective treatment. Some insurance carriers and health maintenance organizations (HMO's) are also establishing similar payment regimens.

Some of the slowing in hospital charges may reflect market adjustments to oversupply of hospital capacity. Between 1978 and 1984, occupancy rates in hospitals declined from 75.5 percent to 72.5,[11] at least partly as the result of shorter hospital stays. The average length of a hospital stay declined from 7.4 days in 1978 to 6.6 days in 1984.[12]

Following their substantial slowdown through 1985, hospital fees began to accelerate again during the first half of 1986. This rather abrupt turnaround is difficult to explain. The possible effects of liability insurance and higher quality care are, of course, factors for hospitals as well as professional services, but there is no obvious reason these effects should have become more pronounced in the first 6 months of 1986.

Table 4. Price change for consumer services other than shelter and energy, 1979–86

Consumer service	Seasonally adjusted annual rate of change (percent)					
	Dec. 1978 to Sept. 1981	Sept. 1981 to Dec. 1982	Dec. 1982 to Dec. 1983	Dec. 1983 to Dec. 1984	Dec. 1984 to Dec. 1985	Dec. 1985 to June 1986
Services excluding shelter and energy	10.1	7.8	4.9	6.0	5.4	6.3
Contributing to overall slowdown:						
Telephone—interstate toll calls	5.5	3.3	1.4	−4.3	−3.8	−11.0
Moving, storage, freight, household laundry, and drycleaning	10.9	7.6	6.2	4.9	7.2	3.1
Appliance and furniture repair	7.5	6.9	4.9	5.6	3.1	3.1
Postage	6.8	7.6	0	0	10.2	0
Apparel services	11.8	6.3	5.0	4.9	4.9	4.1
Automobile maintenance and repair	10.0	6.5	3.8	3.2	3.3	2.6
Automobile finance charges	19.4	−1.9	−7.9	6.8	−8.3	−13.1
Airline fares	28.0	7.7	4.8	6.5	6.3	1.6
Taxi fares	12.7	3.4	2.3	1.2	4.3	2.2
Personal care services	8.4	5.4	3.6	4.9	3.6	3.5
Contributing to slowdown, but remaining high:						
Water and sewage maintenance	8.8	8.3	8.5	5.5	5.5	7.2
Intercity train fares	18.2	12.0	5.5	4.7	4.8	7.5
Intracity mass transit	18.9	5.1	2.1	6.8	3.4	12.5
Professional medical services	10.5	7.3	7.6	6.3	6.5	6.1
Hospital rooms	13.5	14.6	9.3	7.4	4.8	8.3
Other hospital medical care services	13.1	12.0	11.2	7.8	5.2	7.0
Entertainment services	7.2	7.0	5.4	5.7	4.4	6.2
Tuition and other school fees	11.2	12.0	9.4	10.1	8.4	9.1
Personal expenses (bank charges, attorney fees, and funerals)	12.5	13.3	12.2	6.5	6.1	8.4
Contributing upward pressure:						
Telephone local charges	6.4	11.3	3.2	17.1	8.9	16.7
Refuse collection	–	–	–	6.1	6.4	7.8
Automobile insurance	6.2	8.1	9.1	7.9	12.0	13.6
Intercity bus fares	14.3	5.9	7.4	12.3	6.9	14.9
Little meaningful trend:						
Telephone—intrastate toll calls	0.9	5.8	7.4	3.7	.5	.5
Cable television	–	–	–	6.1	6.0	5.4
Automobile rental, registration, and other fees	5.3	12.6	5.9	7.4	3.0	6.2

Many cost containment efforts have been focused on reducing the length of hospital stays and shifting more treatment to an outpatient basis (up from 6.9 percent of hospital revenue in 1978 to 8.8 percent in 1985).[13] While these measures may have the effect of reducing the expenditure for a full treatment, they may actually place an upward pressure on the prices of separate services. On the one hand, higher vacant bed rates do increase the supply of hospital beds and, thereby, may exert some downward pressure on prices. On the other hand, the rather substantial fixed costs for a hospital must now be spread over fewer occupied beds. The final equilibrium price will depend, among other things, on the proportion that fixed costs are of total costs and on the consumer's price elasticity of demand.

The establishment of DRG pricing is intended to lower the total cost for those whose bills are paid by the third-party setting the DRG fee schedule. It is possible, therefore, that over time hospitals may restructure their prices in such a way that larger portions of the fixed costs are borne by those who are not covered by a DRG arrangement. Prices used in the CPI are not generally subject to such arrangements.

It may have taken several months for hospitals to sort out these consequences. As a result, hospital price indexes in the first half of 1986 may be reflecting restructuring of fee schedules to shift costs away from more highly regulated or competitive areas to those with less impact from regulation or competition. While plausible, this explanation is highly conjectural and is offered here primarily due to the lack of an obvious alternative explanation.

Tuition also continues high

Tuition and other school fees have also been slow to respond to the overall decline in inflation. Much of this is an institutional phenomenon. Tuition is usually set well in advance—often as much as 2 years. As a result, both accelerations and decelerations in tuition lag well behind many other price changes. Contributing to the substantial increases in the 1981–1984 period were steps by a number of State legislatures either to reduce funding for State higher education and/or to set higher levels of required student payment.

Intercity train fares have also been boosted as the result of reduced government funding. The Federal subsidy for Amtrak was cut by 4 percent in 85 and by 14 percent in 1986. Nevertheless, reduced fuel costs and competition from the airlines kept fare increases well below their 1979–82 rates.

Water and sewerage maintenance and intracity mass transit have both slowed down from their peak levels. Nevertheless, both continue to have relatively high rates of inflation, despite mass transit charges having benefited from lower energy costs. Because transit and water and sewer services are frequently owned and operated by local government units, the higher-than-average inflation for these services may reflect, in part, the higher-than-average compensation increases for State and local government employees—up 5.8 percent for the year ended June 1986, versus 3.8 percent for private industry workers in the same period.[14] Continued large price increases for refuse collection may reflect not only compensation increases, but also rising "tipping charges" being levied by local government units for use of dump sites and other disposal locations.

Continuing inflationary effects also arise from the charges for local telephone services. The first effects were the direct result of restructuring of AT&T in 1984. Then additional "access charges" were added to local bills in June 1985 and June 1986 as part of the procedure for equalizing both the cost and ease of access among competing long distance carriers and for allocating costs for different elements of the telephone system to the users of those elements. Coincident with the added access charges were partially offsetting declines in interstate long distance charges. Intrastate telephone service is a mixture of (1) toll service supplied by the local operating companies and (2) service provided by long distance carriers. As a result, the index for intrastate toll calls is a mixture of the two factors with no distinct trend of its own.

Auto insurance up sharply

Automobile insurance rates rose at an annual rate of 13.6 percent during the first half of 1986. Not only is this one of the highest inflation rates for items in the CPI, it is more than double the rate which existed in the 1979–81 period. The largest increases have been for the liability portions of auto insurance. A number of reasons have been offered for this. First, accidents are becoming more frequent—up nearly 5 percent between 1984 and 1985, possibly as the result of reduced adherence to the 55-mile-per-hour speed limit.[15] Second, the proportion of accident survivors who are severely injured has been increasing—ironically partly due to increased survival rates resulting from greater use of seatbelts, now mandatory in some States.[16] Third, as in medical care, there seems to be a significant increase in the frequency and magnitude of liability suits.[17] This fact not only increases direct insurance benefit outlays, it also increases uncertainty and carrier reserve levels. Fourth, declining interest rates have reduced insurance carriers' returns on their investments. While reduced interest income requires that additional income must be generated from premiums, the effect for automobile insurance is probably less than for some other types of insurance.

But automobile insurers are also benefiting from some significant reductions in cost pressures. The prices for automobile repair have slowed substantially. And, even though medical costs continue to rise more than many items, they are rising much more slowly than 6 years ago and much more slowly than the automobile insurance costs.

Intercity bus fares also rose at double-digit rates during the first half of 1986—up 14.9 percent. This large increase occurred despite the much more modest rises for the chief competing services—airlines and trains. This apparent anomaly can be understood, at least in part, by realizing that the competition is only partial. First, buses go many places that airlines and trains do not. Bus fares on these, usually shorter-haul, trips are not as constrained by competition. Second, airfares have not moved homogeneously. They have risen most slowly (or even fallen) on the routes with the heaviest competition and traffic. Other routes have had larger fare increases and given buses less competition.

Other commodities

Even excluding the sharp drop in energy prices and lower used car prices, prices for commodities have risen at a much slower rate than those for nonenergy services. This divergence in commodity and service prices suggests that commodity prices in this country may have been affected by lower priced imports resulting from the high value of the dollar relative to the currencies of other countries.

When the dollar was appreciating from 1981 to March 1985, foreign suppliers of imports could receive the same income in their own currency by selling the same quantity of imports at lower dollar prices, as each dollar received by them commanded a greater amount of their own currency. However, it may have taken some time for the rising value of the dollar to have translated into relatively lower costs of imports; a recent Federal Reserve Bulletin article estimated that such an impact may take up to 2 years to appear.[18] The impact of the changing value of the dollar on import prices can be delayed or reduced substantially as a result of changing profit margins of suppliers, the necessity to revise dollar denominated contracts, and specific trade restrictions such as import quotas. Also, changes in the rates of exchange between the dollar and the currencies of the Nation's various trading partners have not been uniform. While the dollar has depreciated significantly against the yen and a number of major European currencies, there has been little change against the currencies of many less developed countries which are significant trading partners. Another point to consider is that the relative price level of imports may be strongly affected by the growth rate of the domestic economy. Although U.S. economic growth has been quite modest, it still exceeds that of many of the country's principal trading partners. Thus, a large number of factors may have intervened to minimize the price-reducing effect of the 1981–85 dollar appreciation, and these same factors may vitiate or delay any inflationary impact of the post-March 1985 devaluation.

From June 1982 through March 1985, as the dollar was appreciating, prices paid by importers for consumer commodities (other than energy, food, and used cars) rose at an annual rate of only 0.7 percent, while prices paid by consumers for the same set of commodities (as measured by the CPI) rose at an annual rate of 3.0 percent.

In the 15 months following the March 1985 peak value of the dollar, these import prices accelerated sharply, rising at an annual rate of 7.9 percent, while the corresponding consumer prices actually slowed more and rose only 2.2 percent. At least for the first 15 months of the dollar's decline, therefore, there was no obvious aggregate effect on consumer prices. Prices paid by importers did not show any obvious impact of the dollar devaluation until the third quarter after it began. After two more quarters, prices paid by consumers still showed no major effects.

Comprehensive analysis relating changes in import prices to changes in consumer prices is difficult. However, some data on price changes have been compiled for nonfood, nonenergy components of the CPI which are judged to have an above average representation of imports in market sales. For each of the 16 commodity groups presented in table 5, import sales constituted more than 10 percent of 1984 total sales.

Table 5 presents annualized rates of change in the commodity price indexes for five periods; price changes shown for the first and last periods were periods of depreciation of the dollar in foreign exchange markets and the others, peri-

Table 5. Seasonally adjusted annual rates of change for Consumer Price Indexes for selected commodities with higher than average import proportions, December 1978 to June 1986

Item	Dec. 1978 to Sept. 1981	Sept. 1981 to Dec. 1982	Dec. 1982 to Dec. 1983	Dec. 1983 to Mar. 1985	Mar. 1985 to June 1986

Other toilet goods and small personal care appliances	9.3	5.3	5.2	3.8	2.9

ods of dollar appreciation. On the one hand, as the dollar strengthened from 1981 to early 1985, one would expect, all other things being equal, that commodities with substantial proportions of imports would exhibit a reduction in prices relative to those of other commodities. That is, while inflation for nonfood, nonenergy commodities on average dropped from 5.1 percent in the early part of the period to 3.5 percent in the latter, one might expect that the price change for commodities with significant import concentrations would slow even more. In fact, only four of these commodity indexes (TV and sound equipment; tableware, serving pieces, and nonelectric kitchenware; lawn equipment, power tools, and other hardware; and toys, hobbies, and other entertainment commodities) showed such a greater reduction.

On the other hand, as the dollar weakened, one would expect that prices for import-affected items would accelerate relative to other prices. Prices for some items have accelerated as one might expect, although quite modestly—for example, tableware, serving pieces, and nonelectric kitchen-ware; toys, hobbies, and other entertainment commodities; wine at home; and new vehicles. But whiskey and other distilled spirit prices accelerated strictly as the result of the imposition of an additional Federal excise tax on distilled spirits in October 1985 and prices for many other items actually slowed or declined more.

The case of new vehicles is an interesting one and illustrates the fact that not only the foreign producer, but also the domestic distributor, may expand profit rates during periods of rising dollar value. During the past few years, it became increasingly common for imported car dealers to add sometimes substantial surcharges because of the limited supply available to them. As the import prices of new cars have begun to rise sharply, there is evidence that dealers are cutting back on their surcharges so that the final prices to the consumer are rising more slowly. While the price paid by the importer rose 14.7 percent in the 9 months ended June 1986, the prices paid by consumers for all cars rose only 3.8 percent. Most of this CPI increase has, however, occurred in the last 3 months.

There is some evidence that a strong dollar may have helped lower inflation and that subsequent dollar weakness may be causing some upward price pressure. Nevertheless, the analysis summarized in table 5 indicates that general exchange rate movements may not serve as a reliable guide in predicting changes in consumer costs for specific products having high import representation, as other factors influencing price change in particular markets may predominate.

Conclusion

The absence of any overall inflation for consumers during the first half of 1986 derived primarily from the sharp decline in petroleum prices. Nevertheless, price moderation was very widespread. On average, cost pressures from materials and labor remained very subdued, and consumer prices for most commodites and many services rose only slightly or declined. The rates of price increase for shelter costs were greater than for overall consumption, but they have been slowing and, based on experience, one would expect that continued moderation in overall inflation will slowly continue to bring them down. The remaining pockets of persistent inflation seem to derive from particular structural factors that may not be very responsive to additional market forces. Among these factors are: reductions in Government subsidies and services, possible cost shifting from regulated activities of an establishment to the unregulated, putative increases in liability litigation, above average increases in compensation for State and local government employees, the court-ordered restructuring of AT&T, and higher rates of nonfatal personal injury in automobile accidents. ☐

[4] "The effect of rental equivalence on the consumer price index, 1967–82," *Monthly Labor Review*, February 1985, pp. 53–55.

[5] There is also limited anecdotal evidence that in some rental markets landlords may be offering special incentives other than lower rents to attract new tenants. Such incentives as reduced security deposits and free merchandise would not be reflected in the CPI rent index.

[6] Residential rent and owners' equivalent rent constitute nearly 92 percent of the shelter CPI. (Other components are maintenance and repair, tenants' and household insurance, lodging while out of town, and college housing.) In addition, while residential rent has usually risen somewhat faster than owners' equivalent rent since 1983, the two series have been quite close.

[7] As in any such analysis, unpredictable external factors can occur. One such potential factor in the coming months is the impending new income tax legislation which some analysts believe may cause upward pressure on residential rent if tax treatment of real estate investment is changed.

[8] The acceleration in these service prices from 1983 to 1984 might suggest the hypothesis that at that point in time there were the early stirrings of renewed economywide inflation. However, it was a very narrow phenomenon; almost the entire acceleration between those 2 years can be attributed to a temporary rise in automobile finance charges and to sharply higher local telephone charges arising from the divestiture of AT&T.

A rope of sand

My job as the president of the A. F. of L. was coveted by no one in the early days. There was much work, little pay, and very little honor. Though the Federation had been created by agreement, it had to be given reality by making it a force in industrial affairs. The necessary first step was to win for the Federation the good will of the wage-earners. The Federation was the unified activity of the trade union men. It was dependent upon good will and understanding of economic power. So I became a seeker of men. I wanted to win them for a labor movement which was sound philosophically, competent economically, and inspiring spirtually. At times I was well-nigh consumed with zeal, so that I gave little thought to anything else. My work was my life. So in recording the events of my life the labor movement is the controlling purpose.

I watched our local unions and gave them suggestions and advice. I fostered the organization of city centrals and State federations. I sent reminders to national officers urging them to pay per capita dues. In the case of national bodies which the Federation had fostered, local unions and members expected me to be a sort of fatherly supervisor of the organization. I wrote letters and talked to officials, diplomatically urging them to performance of duties and constructive policies. I got trade unions to put on their letterheads "affiliated to the American Federation of Labor" and thus helped advertise the name. All this work had to be done in such a way as to win men to the cause. The Federation had no compulsory authority—it was absolutely dependent upon voluntary cooperation.

Spending patterns of older persons revealed in expenditure survey

New estimates point up differences in characteristics, incomes, and expenditures of younger and older populations within the larger group of persons age 65 and over

BETH HARRISON

Interest in the characteristics of older persons is flourishing due to the increasing size of the population age 65 and over. According to projections by the U.S. Bureau of the Census, presented in table 1, every fifth American will be over 65 by the year 2040. This reflects the aging of the postwar baby boom and declining birth rates during the later decades of this century. Clearly, older persons will constitute a rapidly growing political, social, and economic force for many years to come.

Within this environment, new estimates from the Bureau of Labor Statistics Consumer Expenditure Survey (CE) program are likely to be an important tool for trend assessment and policy formation. To date, "65 and older" has been the oldest age class for which expenditure data have been published. (For study purposes, consumer units are assigned to the age category of the householder, or "reference person," as reported on the survey questionnaire.[1]) In recently released estimates, however, that class has been divided into two groups, ages 65–74 and 75 and over. The results reveal that, although persons 65 and over are often viewed as a homogeneous group, the characteristics, incomes, and needs of the younger and older populations within the larger group are actually quite different.

Expenditure differences. Tables 2 and 3 summarize the differences in the 1984 characteristics and spending patterns of the two major subgroups of older Americans.[2] Consumer units in the 65–74 age group spent almost 22 percent more on housing than those in the 75-and-over group. However, housing accounted for a higher *share* of the older group's total expenditures. The expenditure share for fuels, utilities,

Beth Harrison is an economist in the Division of Consumer Expenditure Surveys, Bureau of Labor Statistics.

Table 1. Distribution of the older population by age subgroup, actual and projected, selected years, 1970–2040

Year	Total, 65 and over		65–74		75 and over	
	Number	Percent of total population	Number	Percent of total population	Number	Percent of total population
1970	20,087	9.9	12,487	6.2	7,600	3.7
1980	25,708	11.3	15,647	6.9	10,061	4.4
2000	35,036	13.1	17,693	6.6	17,343	6.5
2020	51,386	17.3	25,968	10.0	25,418	7.3
2040	66,642	21.6	20,228	9.4	46,414	12.2

SOURCE: *Demographic and Socioeconomic Aspects of Aging in the United States*, series P–23, No. 138 (Bureau of the Census, 1984), ch. 2, pp. 5–18, middle series.

and public services was also higher for the 75-and-over group, even though the amount spent was less than that for those age 65–74. The average expenditure on owned dwellings was more than one-third higher for those 65–74 than for the older class. This can be attributed to higher levels of homeownership and a higher percentage of consumer units still paying on their mortgages in the younger group. About 76 percent of those age 65–74 owned their homes compared to 67 percent of the older group. On the other hand, only 8 percent of the homeowners in the older group still owed on mortgages compared to 33 percent of their younger counterparts. There were also large differences in property taxes, for which the expenditures of those 65–74 were 33 percent more than those of the 75-and-over group. This reflects the higher rate of homeownership for the younger group and also suggests they owned more expensive houses or lived in areas with higher property taxes, or both.

Expenditures for transportation accounted for 19 percent of the total expenditures of those age 65–74, compared with 13 percent of the total for those 75 and over. The average expenditures of the former age group were more than twice as high as those of the latter. Much of the difference can be attributed to the higher level of vehicle ownership, 81 percent by those aged 65–74, compared to 59 percent by older persons. It is also likely that vehicles are used less frequently by the older group, further reducing their transportation expenditures.

The data for health care confirms the expectation that both mean expenditures for health care and the health care share of total expenditures are higher for the 75-and-over age group than for their younger counterparts. Health care accounted for 13 percent of the total expenditures of those 75 and over compared with 8 percent of the total for those 65–74.

Income differences. Because income is one of the important determinants of spending, differences in income may help to explain the differences in expenditure patterns. The following tabulation compares selected income components for the age groups.

Sources of income	*Age 65–74*	*Age 75 and over*
Income before taxes	$16,815	$12,442
Sources of income (percent)	100.0	100.0
Wage and salaries	29.3	9.3
Self-employment income	4.6	6.5
Social Security, railroad, and government retirement	52.7	62.9
Interest and dividends	9.6	17.6
Other income	3.8	3.7

The mean income before taxes of the 65–74 age group was more than one-third higher than for persons 75 and over. The largest components of income for both groups were retirement income (consisting of Social Security, private, and government retirement), which accounted for 53 percent of the income of the 65–74 group, compared with 63 percent for the 75-and-over group. Wages and salaries made up about 30 percent of the income of the younger group, which indicates that the reference person or other household member was still working, while it dropped to 10 percent of income for those 75 and over. This is consistent with the fact that the average number of earners is three times higher for the younger group.

The age groups in table 3 differ from those published in regular CE releases. The working age groups, those 25–54, are combined. Older age groups are subdivided into those approaching retirement, those 55–59 and 60–64, and into the two groups that are the focus of this article, those 65–74 and 75 and over.

Since 1980, the Consumer Expenditure Survey has been conducted on a continuing basis. As a result, trends for age and other demographic groups can be more effectively monitored over time. This article is but one of a series highlight-

Table 2. Selected characteristics and expenditure shares for urban consumer units in the age groups 65–74 and 75 and over, Interview Survey, 1984

ing interesting results from the expenditure survey. As the survey continues, additional issues will be covered.

FOOTNOTES

[1] The terms "household" and "consumer unit" are used interchangeably throughout this text. However, the consumer unit definition is the accurate one for this survey. The Consumer Expenditure Survey is described in detail in *BLS Handbook of Methods*, 1982, ch. 6. Survey results are presented in annual reports and bulletins, the most recent of which is *Consumer Expenditure Survey Results from 1984*, USDL 86–258 (Bureau of Labor Statistics, June 22, 1986).

[2] The Consumer Expenditure Survey is composed of two independent surveys: An Interview Survey and a Diary Survey. The results in this article are from the Interview Survey.

European job creation in the wake of plant closing and layoffs

Confronted with massive layoffs in recent years,
firms, and often governments,
have taken a variety of initiatives
to stimulate business growth and job creation

WILLIAM SCHWEKE AND DAVID R. JONES

Over the past decade, millions of American workers lost their jobs through plant closings and work force reductions. According to the U.S. Department of Labor, between January 1979 and January 1984, 11.5 million adult workers were laid off because of plant shutdowns or relocations, abolition of shifts or positions, or slack work. Nearly 5.1 million of these people were considered displaced, having held their former jobs for 3 years or more.[1]

By January 1984, 1.3 million of these workers were still unemployed, and of those, 500,000 had been out of work for 27 weeks or more.[2] Hundreds of thousands more had taken pay cuts and part-time jobs simply to regain employment.

Europe, too, has undergone a massive economic shakeout over the past few years, generating little or no employment growth (in contrast to the increase in jobs in the United States). At the end of 1984, unemployment rates were at double-digit levels in the Netherlands (15 percent), Great Britain (13 percent), and France (10 percent).[3] This economic turmoil has drastically affected certain communities as well. Particularly in the United Kingdom, areas characterized by "mono-industrialism" suffered unemployment levels far above 20 percent.

By comparison, the United States outperformed Europe in creating jobs for its people from 1970 to 1984. From 1974 to 1984, the U.S. economy generated more than 26 million jobs. Of the four largest European nations—with a combined labor market slightly larger than the United States in 1970—West Germany lost close to 1.5 million jobs and Great Britain, 820,000, while France and Italy did better, creating around 380,000 and 1.3 million jobs respectively.

While layoffs and shutdowns proceed on both sides of the Atlantic, the response of government and corporations to the problems created has been significantly more vigorous in Europe than in the United States. American corporations tend to provide, at best, severance pay, relocation assistance, retraining, or job counseling, or a combination of these benefits, for the workers they dislocate. And while the Federal Government will authorize $195 million in 1986 to aid displaced workers through Title III of the Job Training Partnership Act, the program falls far short of helping all those in need, and fails to ensure that enough jobs are created or sustained to employ those trained.

In contrast, European corporations—often working in concert with local, regional, and central governments—in recent years have gone beyond traditional types of assistance to workers and communities.[4] While the programs vary considerably as to methods and scope, they share a common goal of stimulating job creation and new business growth in the wake of economic downturn. By examining both the achievements and limitations of these innovative efforts, American corporations can expand their repertoire of strategies for alleviating the problems of economic dislocation.[5]

William Schweke is vice president of programs at the Corporation for Enterprise Development, Washington, DC. David R. Jones is a freelance writer and editor specializing in public policy.

Effects of streamlining

Across Europe, industrial sectors are experiencing thorough restructuring. In France and Great Britain, for example, nationalized firms have cut their labor forces and increased their productivity through eliminating less profitable facilities and investing in modern machinery. Corporate leaders see most of these changes as positive: many industries are leaner and more competitive, and new types of labor-management cooperation, such as quality circles, are emerging.

Yet, this industrial streamlining has proven devastating to thousands of workers and communities dependent upon corporations for employment. Continued stagnation in employment growth has provoked widespread alarm over the future of job creation. By the end of the decade, more than half of the unemployed in European countries will be long-term unemployed youth.[6]

However, Europeans in business, government, and labor increasingly are seeing entrepreneurship as the key to solving these labor market problems. Public and private corporations are fostering a wide range of business development options, in concert with such adjustment assistance measures as training, early retirement, severance benefits, job placement and development, and financial and employment counseling.

Great Britain, France, and Italy offer the most promising examples of corporate job creation to address economic dislocation. Because the roles of government and unions differ considerably from country to country—and even from plant closing to plant closing—the initiatives discussed in this report will be examined in the context of their national economic circumstances. Having assessed the successes and failures in each country, we then will note the patterns that cut across national boundaries and discuss the implications for U.S. public policy.

Great Britain

Great Britain has endured continued high levels of unemployment since 1980. While the government of Prime Minister Margaret Thatcher has pursued some direct employment measures, it is corporations that have spurred the most successful initiatives. In the process, these companies have learned the value of forming partnerships with local and regional governments and voluntary organizations to achieve their goals.

BSC Industry, Ltd. This program, begun nearly a decade ago by the country's nationalized giant, British Steel Corporation, serves as Europe's showcase example of job creation and new business formation. BSC Industry was established as a wholly owned subsidiary of the company to create jobs in communities and regions hit by steel mill closures (British Steel slashed its work force from 225,000 workers in 1975 to 71,000 employees in 1985).

BSC Industry initially focused on recruiting other large firms to distressed areas. This approach has gradually given way to a broader range of efforts targeted to smaller firms and would-be entrepreneurs. The subsidiary, which became independent of British Steel in 1984, now operates in 18 steel-mill closure areas. Its activities include marketing new images for depressed steel communities ("opportunity areas") to provide a supportive climate for indigenous business development and to attract outside employers; providing comprehensive business assistance, including seed financing and loans, to new and existing firms; converting outdated facilities into incubators (or "workshops") for entrepreneurs; and encouraging the formation of independent and public-private partnerships—known as Local Enterprise Agencies—to bring together community resources in a united effort to regenerate distressed steel communities. BSC Industry has merged its technical assistance operations with those of the Local Enterprise Agencies.

From 1975 to 1984, British Steel committed about £40 million to BSC Industry's activities. The results have been impressive: 2,000 companies have been assisted in creating 30,000 new jobs, with another 20,000 jobs to be filled in the near future. Eight entrepreneurial workshops house hundreds of businesses. The organization's loan programs provide crucial gap financing that the private sector has been unable to provide to more than 200 firms, with £8 million to £9 million out at any one time; 90 percent of the loans are equal to or less than £25,000 (approximately $17,361).[7]

Scottish Development Agency. This is another organization taking a broad approach to the problem. The Scottish Development Agency was formed in 1975 by the merger of the Scottish Industrial Company with the National Investment Bank. It focuses on local small business development through factory building, management and marketing assistance, gap financing, and youth entrepreneurship development. One project, the Clydebank Enterprise Fund, has loaned nearly £700,000 (around $486,108) to 50 local companies, most of them new business start-ups; over £2 million have been leveraged.

Private corporate activity. United Biscuits, British American Tobacco, and the glassmaker, Pilkington Brothers, have followed BSC Industries' approach and now offer financing, comprehensive business assistance, and unused land and buildings to small firms in communities hit by shutdowns. In plant closure situations, United Biscuits has financed local economic and community development feasibility studies, as well as provided "challenge grants" to match local job creation resources. It supports project Fullemploy, which provides intensive training, mainly for ethnic minorities, for retail and sales work and boasts a 70-percent placement rate.

France

In France, larger firms must receive government approval before closing plants. Companies must offset the resulting job loss with job creation efforts. Thus, in contrast to Great Britain, the central government and unions in France serve as the main catalysts for responses to economic downturn. Nevertheless, a number of French firms like the Thomson Group, the BSN Group, St. Gobain, Rhone Poulenc, Elf Acquitaince, and others, have gone far beyond mere adjustment assistance.

SOFIREM. The country's nationalized coal company, Charbonnages de France, has pioneered efforts to rebuild distressed industrial communities through its job creation subsidiary, SOFIREM (Societe Financiere pour Favoriser l'Industrialisation des Regions Minieres). The central government empowered SOFIREM to offer a financial package of equity, loans, and subsidies to entice large firms to distressed coal communities. In addition, SOFIREM helped create 30 businesses in 1984 and another 30 in 1985, and plans on fostering another 70 over the next 2 years. Its Industrial Fund uses 300 million francs (approximately $43 million) annually for constructing buildings, promoting exports, providing training, and conducting feasibility studies.[8]

SOPRAN. Rhone Poulenc, a large chemical company, created SOPRAN (Societe pour la Promotion d'Activites Nouvelles) as a separate company in the late 1970's to create employment for workers it laid off. Along with providing adjustment assistance—early retirement for former employees 55 years and older and transfer rights to displaced employees—SOPRAN is currently helping about 40 people start their own firms. More than 1,200 new jobs have been created through SOPRAN'S efforts—about half of them going to former employees, a much higher ratio than BSC Industry has achieved. Each job has cost Rhone Poulenc roughly 65,000 francs ($9,312), a small sum compared with the cost of similar programs in other countries.[9]

St. Gobain. This company, which produces products for automobiles and construction, provides transfer assistance to displaced employees and technical and financial assistance to developing, small- to medium-sized firms. Working through five decentralized regional delegations, the St. Gobain Development Service has helped 230 businesses, creating 5,050 jobs, over the past 3 years. Of these firms, about 150 were established, growing companies, while 50 were start-ups, and 30 were new businesses attracted.[10]

Loans are typically extended for 10 years at the modest interest rate of 6 percent. The size of the loan is geared to the number of jobs involved, with the company aiming to spend 10,000 to 50,000 francs ($1,432 to $7,163) per job. If a former employee of St. Gobain is hired, the loan is changed into a direct grant.

Italy

Montedison. In Italy, as in France, the central government and unions provide most of the impetus for corporate job creation. A major exception is Montedison, a large diversified firm, that, on its own, has undertaken broad efforts to aid small- and medium-sized firms. Montedison helps small businesses in economically depressed southern Italy to qualify as its suppliers. It also assists new and established businesses throughout Italy, regardless of whether they are in industries related to Montedison's products or needs. Unlike many other European business assistance programs, Montedison shies away from financing in favor of providing such services as regulatory assistance, infrastructure design, and foreign marketing.

ENI. The giant petrochemical conglomerate ENI (Ente Nazionale Idrocarburi) has worked since 1978 on promoting industrial diversification and providing alternative employment for laid-off employees. Its activities center on aiding small and new businesses. Working in eight "crisis areas," ENI has helped create 1,000 jobs and has provided vocational training for another 3,400 workers.[11]

Implications and possibilities

Perhaps most importantly, these new European initiatives show that corporations and governments can considerably expand their efforts to launch enterprise and job creation programs in response to industrial restructuring. In America, best corporate practices focus only on picking up the pieces after closures, whereas the European efforts cited the way to moving from mere reaction to proaction.

Second, the most successful of these efforts indicate ways for corporations to integrate social responsibility into mainstream business operations. By synthesizing their longer-term business strategy with their employment and adjustment concerns, corporations can find ways to serve their goals of launching new products and services, developing new business ideas, improving employee morale, encouraging entrepreneurial initiative, and maintaining good public relations. The success of SOFIREM in France and Montedison in Italy demonstrates how closely these concerns can be integrated.

Third, as the Organization for Economic Cooperation and Development has noted, companies have found that their natural partners in employment initiatives are local government and voluntary organizations.[12] Prior involvement in community affairs and knowledge of the local political situation and its actors are crucial. From the partnerships between schools and industry that United Biscuits has forged, to the Local Enterprise Agencies that BSC Industry created, Great Britain has taken the lead in this area.

Fourth, the European actions suggest possibilities for union and community negotiations over closings. The initiatives serve as precedents for crafting either formal closure agreements or flexible responses to the impending problems that closures will generate.

Finally, a closely related point is the importance of prior notice of layoffs and shutdowns. This not only gives companies time to build partnerships with unions and communities; it is essential for giving firms enough lead time to develop and launch new businesses. Being a day late may mean being a dollar short. SOPRAN reports that is takes at least 18 months to get a new plant into operation.[13] Graham Ledger of United Biscuits in Great Britain notes that his company gave a 3-year closure notice for its Liverpool facility, and, "We think we did it right."[14]

Limitations

Like its achievements, Europe's problems with job creation are instructive. The chief barrier which European corporations have confronted is the nature of entrepreneurialism; it cannot solve all problems, nor should it be expected to do so. In particular, most initiatives have failed to integrate large numbers of blue-collar workers and their concerns into operation. Even BSC Industry has had very limited success in creating new jobs for displaced steelworkers.[15] Indeed, the program's leaders see its role as creating jobs in closure-affected communities, not as finding employment for displaced steelworkers.

This means that small and new business development must be complemented with more traditional strategies. For example, the Clwyd County Council and British Steel Corporation Industry in Great Britain and SOFIREM and St. Gobain in France have succeeded in attracting major new firms to their areas to supplement their work in indigenous business development.

Management problems pose a second major limitation. Many initiatives rely on inadequate assessments of local assets and liabilities. Then, too, the responses to problems tend to become formulaic; over and over, the same techniques—seed capital, workshops, and technical assistance—are used. New, riskier programs—such as the Clywd County Council's Project Live Wire for training young people as entrepreneurs—offer the promise of breaking the mold.

A third limitation arises from the very depth of the economic dislocation problem. In many communities, the amount of job creation is dwarfed by the numbers of jobs lost. The Organization for Economic Cooperation and Development (OECD) argues that it is impossible to estimate the number of jobs created by these initiatives. For instance, it is difficult to even define the terms "durable" job and "new" job. However, the Organization states that "it is hard to imagine that corporate job creation schemes have to date yielded much more than 100,000 new jobs in the whole of Western Europe."[16] Furthermore, it is virtually impossible to measure the number of second- and third-wave jobs created when new businesses start up.[17] In any case, these new initatives can only deal in limited ways with the underlying causes of closures and dislocation. (See box.)

Initiatives for Local Employment Creation

The growth of the Initiatives for Local Employment (ILE) program has been spearheaded by the failure of traditional solutions developed by central governments which attempt to produce satisfactory responses, let alone solutions, to the unemployment problems. The ILE program is run by a small team within the Organization for Economic Cooperation and Development (OECD) secretariat. Its function is to encourage cooperation, exchange, and analysis between the different participants in the program who meet regularly as the ILE's directing committee. The program's secretariat proposes and undertakes research and action; encourages and organizes the exchange of ideas, experience, and people; and assists countries in realizing the objectives of the program.

Taking part in the program are: Australia, Austria, Belgium, Canada, Denmark, Finland, France, Germany, Greece, Ireland, Italy, the Netherlands, Norway, Portugal, Spain, Sweden, Turkey, the United Kingdom, and the United States, and the Commission of the European Communities. Japan is an Observer Member.

The sharing and exchange of information and experience is a central and continuing part of the ILE program's work. This activity will increasingly provide a network of interested innovators with information drawn from seminars, case studies, and special studies. This information will be diffused through a liason letter as well as through a series of publications—ILE Notebooks. In the long term, it is planned to establish an advanced communications system linking internationally a wide network of groups and individuals involved in local employment initiatives.

The ILE program welcomes any initiatives, ideas, proposals, or information. Also, any requests for documentation or arranging contracts should be addressed to:

OECD ILE Programme
2, rue du Conseiller-Collignon,
75116 Paris
France

Problems in corporate dealings with unions and local communities present a fourth limitation. Understandably, both labor and management often feel compelled to debate the plant closure decision itself, preventing the timely development of contingency plans for creating new jobs. Similarly, many projects fail to involve other community actors and neglect the creation of new, community-based institutions to carry forward a longer-term renewal strategy.

Finally, disseminating these models to the United States requires considerable translation. European corporate leaders see themselves as responsible to a broader set of stakeholders than do their American counterparts, who tend to weigh shareholder concerns more heavily.

New corporate roles

While altruism plays a role in the European initatives discussed, time and again, corporate leaders in the three countries cited corporate self-interest as a motivating factor. Targeted business investment can help diminish pressing social problems that, if neglected, eventually can undermine business profits and long-term investment opportunities.

Such investments may prove especially important in layoff situations where firms plan to maintain operations. This not only generates goodwill among labor and the community, but also helps prevent the local business climate from unraveling to the point where the costs of doing business increase and retaining quality management and employees becomes prohibitive. As an executive of the British firm Pilkington Brothers noted, "You can't operate behind barbed wire. You can't operate in an area with 30 percent unemployment. You have to deal with the problem."[18]

Most of the job-creating tools, including incubators, technical and financial assistance, and entrepreneurial training, are already in place in the United States; in fact, options such as venture capital are far more abundant here than overseas. What is needed by American leaders is an understanding of how specifically to apply these tools in ameliorating the devastating effects of layoffs and shutdowns. This report provides an introduction to these development tools. The detailed work on their application should be written by corporate and government leaders themselves. ☐

[4] Obviously, U.S. companies have been very active in the corporate responsibility and enterprise development fields for a number of years and have, in fact, been in the vanguard. American corporate philanthropic practice dwarfs that of Europe. (One of the principal reasons is that Europe's much more extensive safety net has not encouraged the development of this sector.) Yet, despite U.S. pathbreaking actions in urban development, antipoverty initiatives, and so on, these efforts have not focused on the issues of economic dislocation. Instead, initiatives from corporations like the Control Data Corporation to create small business incubators have been responses to the broader problems of new technology development and small business assistance. The sole U.S. exceptions are the Brown and Williamson Corporation which paid for a reuse plan for a closed facility in Petersburg, VA, and Levi Strauss and Company which hired The Corporation for Enterprise Development to develop an economic development feasibility study in two communities in rural Tennessee where they closed branch plants.

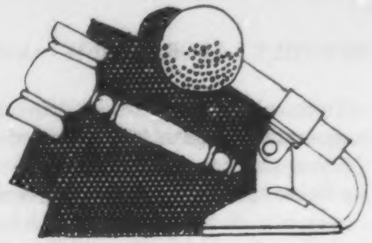
Conventions



Constitutional convention marks golden anniversary of the UAW

HENRY GUZDA

The United Automobile, Aerospace and Agricultural Implement Workers of America (UAW) ended a 2-year celebration with the close of their 28th constitutional convention (UAW conventions are triennial), held June 1–6, in Anaheim, CA. It marked the culmination of the UAW's golden anniversary (1935–85), 50 years of social and economic progress. The celebratory theme, "We make our own history," was replete with allegories and accounts of the union's existence, highlighted by an episodic pictorial exhibit of that struggle: photos of the 1937 sit-down strike against General Motors; pictures on the beatings delivered to union organizers Walter Reuther and Richard Frankensteen in the infamous "Battle of the Overpass"; scenes of production lines manned by UAW-CIO members who helped to make the U.S. Army "go and grow" during World War II; and photos spanning a decade of activism by the UAW in the civil rights movement. Every guest speaker and union official invoked the name and memory of past heroes and events.

The union's stormy past reflected poignantly on an equally turbulent present. Thousands of auto industry jobs have shifted to foreign shores, and many American automakers have asked the union for further sacrifices in the form of collective bargaining concessions to remain competitive in a global economy. The new industrial relations system (a term to describe the current mode of cooperative labor-management relations vis-a-vis an adversarial one) has confused and upset some rank-and-file UAW members, provoking emotional debate among the 2,500 delegates over the union's survival strategy. Complicating these internal problems was the decision by all but one of the UAW Canadian locals to secede and form their own union, the Canadian Auto Workers (CAW-Canada).

The convention climate, however, was upbeat and confident. Elected for a second consecutive 3-year term, UAW President Owen Bieber vowed to "go to war" to protect the union cause. While acknowledging the existence of internal union dissension caused by the tenor of troubled times, Bieber exclaimed that the "U" in UAW really does stand for "United." Industrial cooperation in today's economic world, he added, is imperative but also a two-way street.

Fair trade, a key issue

High on the UAW list of convention priorities was the American trade imbalance and the erosion of our industrial base. The auto industry has lost 400,000 jobs to foreign competition since 1980, and the delegates place much of the blame on trade policies. The delegates supported several resolutions calling for a national industrial policy to increase our competitiveness with low wage standard nations and encourage productivity in the United States, including the general "Resolution on International Trade and Related Matters." This resolution supports domestic auto content legislation, recognition of unfair trade practices, trade adjustment assistance for U.S. workers displaced by foreign competition, affirmative Federal action to protect U.S. jobs, and penalties against nations which disregard worker rights.

The trade resolution also called on the Federal Government to protect the American industrial base. The shift in emphasis to service and information sector jobs—which organized labor views as low paying jobs—is detrimental to the U.S. economy, stated several delegates from the floor. The delegation also voiced support for H.R. 4800, a trade bill passed by the U.S. House of Representatives and awaiting action by the U.S. Senate, that they believe will remedy some of the problems addressed at the convention.

Other convention speakers also focused on this theme. Senator Howard Metzenbaum, from a "rust belt" State with serious employment and trade problems, told the gathering that worker solidarity on a national industrial policy was imperative because nations with even lower wage rate structures than our current chief competitors are planning to export autos to the United States. Murray Finley, president of the Amalgamated Clothing Workers, reminded the delegates that all of U.S. industry faces this problem, and Shiro Umemura, acting president of the Japanese Auto Workers, underscored the need for global worker solidarity. Bieber had previously educated the audience about current and future plans by Brazil, Yugoslavia, The People's Republic of China, and South Korea, all with auto worker wage rates under $1 an hour, to export cars to the United States. Herman Rebhan, General Secretary of the International Metal Workers Federation—a body of auto worker and related trades organizations in the noncommunist world—discussed the lack of worker rights in these nations. The trade resolution calls for denial of favored-nation status to polities like Korea because of worker rights violations.

Henry Guzda is an industrial relations specialist with the Bureau of Labor Management Relations and Cooperative Programs, U.S. Department of Labor.

To complement the message delivered from the speakers' podium, the delegates held a spirited floor demonstration. Carrying placards calling for Federal support of plant closing legislation, protection against pension plan failures, and support of trade bill H.R. 4800, the delegates paraded around the convention floor while a speaker read out the names and locations of the participating locals: a litany of rust belt cities and towns. The demonstration was organized by the UAW's Industrial Parts Supplier Department, whose members have been deeply affected by the use of foreign parts in auto manufacturing. The resolution was vociferously adopted by the delegates.

Internal affairs

The UAW's reputation for honesty and internal democracy has been tarnished by recent events, but the convention quickly reapplied the lustre. Most embarrassing for the union was the conviction of Frank Runnels, director of region 1-E, for taking kickbacks from workers' compensation lawyers. The UAW executive board removed him from office following the conviction and confirmed their decision at the convention by consolidating region 1-E with region 1-A under director Earnest Lofton. The convention condemned Runnels' betrayal of his stewardship.

The union conducted additional housecleaning. Several officials from Chicago were reprimanded by the UAW Public Review Board, an oversight body of distinguished academics, for improper administration of pension funds. No other major union has such an internal oversight body.

More damaging in substance than reputation was the secession of the Canadian locals from the UAW. In 1984, Canadian auto worker locals, under the direction of UAW Vice President for Canada Robert White, requested broad autonomy in the administration of their affairs. The UAW executive board ruled the request excessive and demanding of more powers for White than were endowed to international President Bieber. Consequently, the Canadians established *de facto* independence in 1985, and made it *de jure* through the formal procedures of the convention. Amended constitution article 53 transferred property and more than $30 million to the new CAW-Canada. The UAW lost about $15 million per year in dues, but retained its international status through the Wallaceburg, Ontario, Local 251, with 1,800 members, which voted to remain in the Detroit-based union.

President Bieber and the delegates prologued the amicable separation, extending a friendly hand to the new union and promising to keep the lamp of hope lit for a future reconciliation. The departure of 120,000 Canadian members drops UAW membership to about 1.1 million, the lowest total since 1961.

The issue of Canadian autonomy reflected upon a proposed resolution for direct elections of union officials. Twenty locals submitted 31 resolutions on the adoption of a referendum system to replace the convention/delegate system. Proposals ranged from simple direct rank-and-file voting for international officers to conducting referenda on all important issues. Supporters argued that a change would stimulate internal democracy and make the international leadership more responsive to the wants and needs of grass roots membership. They blamed the convention system for encouraging abuses in some other international unions.

However, the constitutional committee of the convention encouraged retention of the existing system. Referendum voting, they argued, could engender constant factionalism and infighting which might open the UAW to monitoring by government agencies or other bodies. They believed incumbents would have unfair advantages which might lead challengers to seek assistance from sources not having the best interests of the union as a priority. According to the committee report, only two major unions, the Steelworkers and Mineworkers, still utilize the referendum system; the Electrical Workers union (IUE) switched to the convention format in 1978 to alleviate administrative problems. Considerable debate followed the committee report, and the convention eventually agreed to retain the current system.

Appropriately, the elections procedure debate fueled the controversy in a particularly intense contest for director of UAW region 5, comprising south central States. Incumbent Ken Worley defeated insurgent candidate, and onetime assistant, Jerry Tucker by a single vote, 325–324. Tucker's "New Directions" movement contested the eligibility of several delegates and convinced the entire convention to postpone Worley's installation as regional director until the credentials committee could rule on the matter. After deliberation, the committee upheld Worley's election by an official tally of 324.577 to 324.416 (fragmented voting is common under the delegate system). All other regional directorships were decided by acclamation, except for one noncontroversial race.

At the international level, Raymond Majerus was reelected secretary-treasurer, with Odessa Komer, Marc Stepp, Stephen Yokich, and Donald Ephlin retaining their respective vice presidencies. An attempt to remove Ephlin from office because of opposition to the Saturn agreement (discussed below) which he engineered failed when the dissidents' nominee refused to challenge. The delegates voted to increase the salaries of the president (from $74,893.97 per year to $82,268.76); the secretary-treasurer (from $67,252.05 to $74,359.37); international executive board members (from $56,634.97 to $63,360.34); and international representatives (from $42,227.51 to $48,151.12).

Cosmic controversy

Paradoxically, the issue stimulating the most controversy and debate was one that procedurally belonged in the realm of a collective bargaining convention, not a constitutional one. Saturn, the name of both an innovative collective bargaining agreement and the new subsidiary corporation of General Motors, proposes to operate an auto factory in Spring Hill, TN, utilizing a cooperative labor-management relations process. Workers will receive a salary in lieu of hourly wages, estimated at 80 percent of the industry average wage, but will be eligible for performance bonuses. Under the participatory management provisions of the agreement, workers will have positive roles in company decisionmaking. Another key provision of the contract is protection against layoffs. Also, management can utilize workers in a variety of job categories because the myriad of job classifications in the traditional auto factory have been greatly reduced.

Some dissidents charged that this departure from the traditional collective bargaining process places the worker on "the sacrificial altar of industry domination." It is concessionary, they charge and, citing the many violent struggles the union has fought to get current wage and benefit levels, insist that it endangers the future existence of the trade union movement. Victor Reuther, a UAW cofounder, has served as the symbolic leader of this group.

Under article 19 of the union's constitution, the dissidents succeeded in getting the floor to debate Saturn. Delegates Peter Kelley of Local 160 and Al Gardner of Local 600 argued that the article's section 3 prohibited union officials from negotiating contracts without prior approval and ratification by workers in the collective bargaining unit. Given that the workers for Saturn have not been hired, they claimed the agreement was invalid. In addition, they challenged the agreement for violating section 6 of the same article which states that the executive board shall not encourage rivalry among locals and shall protect superior agreements. Gardner charged that Saturn allowed "whipsawing" of one local against another because its concessionary provisions would cause employers to demand similar contract concessions from other locals. The protests noted that officials of Chrysler Corp. and General Motors have hailed the future "Saturnization" of the auto industry.

The Saturn debate lasted 2 hours and extended the convention well past the scheduled recess time, with the delegates eventually voting to table the issue for the proper forum of the 1987 collective bargaining convention. But the catalyst for convention action was Bieber. He pleaded with the delegates not to tie the hands of the executive board by abrogating the agreement and thereby create another unorganized auto plant. The Saturn experiment was a conduit through which the UAW would get its foot in the door of a right-to-work area and then branch out to organize the nearby Nissan factory in Smyrna, TN, and the proposed Toyota plant in Georgetown, KY. Citing the joint GM-Toyota venture in Freemont, CA (New United Motor Manufacturing, Inc.), Bieber reminded the convention that the UAW members working there would have lost their jobs to plant closure if not for the implementation of a cooperative concept. He also reminded the dissidents that Chrysler Corp. failed to get Saturn-like agreements in collective bargaining contracts negotiated in 1985, and that once hired, the work force at Saturn could vote to change conditions. The delegates supported Bieber. (As the UAW debated the issue, the National Labor Relations Board upheld the UAW-Saturn pact as legal and not in conflict with Tennessee right-to-work or Federal laws as charged by the National Right-to-Work Committee.)

A milder controversy arose over the question of dues payments. A resolution called for supplemental funding for the UAW Walter and May Reuther Educational Center in Black Lake, MI, appropriated from dues payments. Dues are collected on 2 hours pay per month for each individual and surpluses over the $500 million strike fund are rebated to locals. Some delegates, not opposing aid for the educational center, used the opportunity of debate to criticize procedures approved at the 1983 convention for taking extra dues from members based on bonuses and profit-sharing amounts. The anti-Saturn delegates charged that this system aided the cause of employers who desired bonuses and profit-sharing pay increases over the annual improvement wage plan. A third protest contingent argued that bonuses and profit-sharing sums were not wages and should not be considered in dues payments. Protests notwithstanding, the delegates voted to accept the resolution designed by the constitutional committee for additional funding of the educational center and continuance of the dues system adopted at the 1983 convention.

Other resolutions were recommended and adopted with little controversy. The UAW reaffirmed its commitment to social and economic progress by supporting women's rights, the concerns of the needy, civil rights, protection of the environment, and similar concerns.

Solidarity forever

Historically, the UAW has sought to build bridges of cooperation with others in the labor movement. This convention reinforced that effort. The UAW cancelled reservations at the Disneyland Hotel to honor picket lines of the Hotel Employees and Restaurant Employees Union, depriving the struck hotel of an estimated $600,000 in revenue. The convention promised more assistance for distressed unions as when the UAW sent supplies to the flood ravaged coal miners of West Virginia in 1985.

Just as important was the international flavor of the convention's call for worker solidarity. The UAW invited trade unionists from 16 countries to attend, including Yugoslavia, Malaysia, India, and South Africa. Resolutions were adopted condemning supression of workers' rights in Poland, South Africa, and Chile.

Bieber's keynote address contained a fitting summation for this convention and the end of the first 50 years of the union. "Brothers and sisters," he said, "there have been dark moments along our 50 years of struggle. By ourselves, we could not have survived, let alone prospered. We did—because we stood together." He then closed by paraphrasing labor's anthem, Solidarity Forever, stating, "together there is no power greater anywhere beneath the sun, for the UAW makes us strong." ☐

Research Summaries

BLS white-collar pay survey now covers small firms

JOHN D. MORTON

Clerical workers and recent hires in professional and administrative positions typically are paid 10 to 20 percent more in large firms employing 2,500 workers or more than in small firms employing 50 to 999 workers. In contrast, the pay advantage for fully experienced professionals in these large firms is usually under 5 percent. (See table 1.)

The national survey of professional administrative, technical, and clerical pay (PATC survey) in 1986 increased its coverage of firms with as few as 50 workers. As a result of the expansion, 156,000 establishments employing 33.5 million workers were covered in 1986 (previously, the survey covered 47,000 establishments employing 23.3 million workers). Establishments in Alaska and Hawaii are excluded. The survey is conducted by the Bureau of Labor Statistics, but survey occupations and coverage, such as establishment size and the private industries to be included, are determined by the President's Pay Agent (the Secretary of Labor and the Directors of the Office of Management and Budget and the Office of Personnel Management).[1]

In addition to the size of a firm's work force, skill and experience also influence white-collar pay, as can be readily seen from the survey results. (See table 2.) Engineers, the survey's most numerous occupational group, illustrate the effect of rising skill levels on pay: recent engineering graduates (level I) averaged $27,866 annually in March 1986, while engineers responsible for highly complex engineering programs (level VIII) averaged $79,021.[2]

In contrast, skill levels can act as a source of pay uniformity for the same level of work among different occupations. The following tabulation shows a relatively narrow (9 percent) spread separated the highest paid and lowest paid of six equivalent work levels in the survey:

Work levels	*Annual salary level*
Attorney IV	$63,933
Director of personnel III	63,855
Chief accountant III	62,880
Accountant VI	61,546
Chemist VI	60,796
Engineer VI	58,883

Table 1. Relative pay levels by size of establishment, selected white-collar occupations in the national survey of professional, administrative, technical, and clerical pay, March 1986

Job classification	Mean salaries for establishment size groups as a percent of surveywide averages			
	All establishments	50 to 999 workers	1,000 to 2,499 workers	2,500 workers or more
Accountants I	100	96	104	107
Accountants III	100	98	101	107
Accountants IV	100	99	101	102
Engineers I	100	93	102	104
Engineers III	100	97	104	101
Engineers IV	100	98	103	100
Computer programmers I	100	94	102	110
Computer programmers III	100	97	98	104
Computer programmers IV	100	96	98	102

NOTE: Level I staff are trainees; level III are experienced nonsupervisory staff working on conventional assignments; and level IV are experienced staff working on more complex assignments in a supervisory or nonsupervisory capacity.

Unequal market demands, however, can nullify this cluster effect. For example, average pay for beginning engineers in the survey was well above that of their accountant and chemist counterparts.

Although the PATC survey focuses on salary levels at a given time, its history permits a look at salary trends. White-collar salaries increased moderately between March 1985 and March 1986 in medium and large firms. Average salaries for most occupations surveyed rose between 3.0 and 5.5 percent—in line with gains reported a year earlier. In contrast, occupational salary increases averaged about 7 percent a year during the 1970's and more than 9 percent in 1981 and 1982. However, the rate of increase has been declining since 1982.[3]

A detailed analysis of white-collar salaries and complete results of this year's survey are included in the *National Survey of Professional, Administrative, Technical, and Clerical Pay, March 1986*, Bulletin 2271 (Bureau of Labor Statistics, 1986). The bulletin contains, for example, separate salary data by size of community and size of establishment. ☐

[1] Occupational employment estimates relate to the total in all establishments within scope of the survey and not to the number actually surveyed.

[2] Excludes premium pay for overtime and for work on weekends, holidays, and late shifts. Also excluded are performance bonuses and lump-sum payments of the type negotiated in the auto and aerospace industries, as well as profit-sharing payments, attendance bonuses, Christmas or year-end bonuses, and other nonproduction bonuses. Pay increases—but not bonuses—under cost-of-living clauses and incentive payments, however, are included.

NOTE: The following occupational levels were surveyed but insufficient data were obtained to warrant publication: chief accountant I and V; director of personnel V; chemist VIII; computer programmer VI; and personnel clerk/assistant V. Published in 1986 but not in 1985 are photographer V, a new first level of purchasing clerk/assistant, and a newly added series of general clerks.

[2] In the survey coding structure, the level designations among various occupations are not synonymous: for example, the first level of attorneys equates to the third levels of engineers, accountants, and most other professional and administrative occupations. Classification of employees in the occupations and work levels surveyed is based on factors detailed in definitions which are available upon request.

[3] For a broader-based picture of wage and compensation trends in the United States, see the *Employment Cost Index*, a BLS quarterly news release.

What happened to the high school class of 1985?

SHARON R. COHANY

Almost 3.3 million youths either graduated from high school or dropped out between October 1984 and 1985.[1] The proportion of graduates who enrolled in college set a record.[2] Graduates who did not attend college were typically in the labor force, and their unemployment rate was 11 percentage points lower than the 36-percent rate recorded for those who dropped out of high school and entered the labor force. The differing labor market experiences for these three groups highlight the fact that youth with educational deficiencies typically encounter work-related problems which may last for the rest of their lives.

Going on to college

Reflecting the declining school-age population of the "baby-bust" generation, the high school graduating class of 1985 was smaller than those in recent years. A total of 2.7 million young people graduated from high school, down half a million from the peak reached in the mid-1970's. (See table 1.) Despite the smaller number, the proportion of seniors going on to college has been rising gradually over the past few years. It reached a record 58 percent in 1985, after hovering between 50 and 55 percent for most of the 1970's and early 1980's. (See table 2.)

Sex. In recent years, college enrollment rates for men and women just out of high school have drawn closer together, eliminating the wide differences that existed in the early 1970's. By 1985, enrollment rates for men and women were 59 and 57 percent, respectively. The rate for men had returned to the high levels recorded during the early 1970's—the tail end of the Vietnam-era's military draft—while that for women was at its highest level ever.

Once enrolled in college, men and women have roughly the same labor force participation rates—around 44 percent. Despite substantial increases in tuition and other college expenses, this overall participation rate has changed little since the late 1970's. Grants, loans, family contributions, and summer earnings have continued to enable a majority of full-time students to stay out of the labor force during the school year.[3] (See table 3.)

Race. A large gap still exists in the proportion of black and white high school graduates who go on to college. In October 1985, the proportion of enrolled black seniors was 42 percent, compared with 59 percent for whites. Despite some improvement over the last few years, the black proportion was still well below their 46- to 48-percent range during the 1970's.

Large differences by race also persist with regard to labor force participation. Only 31 percent of the black college enrollees were in the labor force, compared with almost 47 percent of the whites. One reason for this difference was that a higher proportion of black students were enrolled in 2-year institutions, which are, on average, less expensive than 4-year colleges and universities.[4]

Not going on to college

About 1.1 million members of the class of 1985 did not enroll in college. Their overall rate of labor force participation was 82 percent, somewhat lower than that prevailing during the past decade. Participation rates for men in this category were higher than those for women, and rates for whites were higher than those for blacks and Hispanics.

The incidence of unemployment for these high school graduates in the labor force has drifted upward during the 1980's. In 1985, about 1 of 4 were looking for work, compared with around 1 of 6 during the 1970's. Thus, despite a shrinking youth population and less competition for entry-level positions, young people who end their formal education with a high school diploma still have a hard time finding jobs. In part, this may result from the increasing demands of employers for better educated workers, given the higher educational level of the work force and a surplus of college graduates in some fields.[5]

High school dropouts

A total of 612,000 youths dropped out of high school between October 1984 and 1985. This was about the same number as in the previous 2 years, but lower than in the 1970's, reflecting mainly the declining teenage population.

Male dropouts were much more likely to be labor force participants than the women, a fourth of whom had family responsibilities. One study showed that many of the young women who dropped out of high school as sophomores in 1980 gave such family-related reasons as marriage or plans to marry (31 percent), pregnancy (23 percent), and the need to support a family (8 percent).[6]

Leaving school before graduation particularly affects the labor force participation of black youth. While 72 percent of the white dropouts were in the labor force, only 52 percent

White	458	330	72.1	214	116	35.2
Black	132	69	52.3	39	30	(2)
Hispanic origin	106	73	68.9	40	33	(2)

[1] Data refer to persons who dropped out of school between October 1984 and October 1985. In addition, 80,000 persons 14 and 15 years old dropped out of school during this period.

[2] Data not shown where base is less than 75,000.

NOTE: Detail for the above race and Hispanic-origin groups will not sum to totals because data for the "other races" group are not presented and Hispanics are included in both the white and black population groups. Because of rounding, sums of individual items may not equal totals.

of the black dropouts were. This was a much wider spread than for the graduates not enrolled in college.

Reflecting their relatively low skill and experience levels, recent dropouts have extremely high unemployment rates, nearly 36 percent in 1985. This jobseeking rate has averaged 35 percent thus far in the 1980's, compared with a 27-percent average in the 1970's. In this respect, the jobless picture for dropouts has paralleled the upturn in the unemployment rate for workers in general, although at much higher levels.

Table 2. Percent of recent high school graduates 16 to 24 years old enrolled in college, by year of graduation, sex, and race, selected years, October 1970–85

[Numbers in thousands]

Year	Total graduates	Percent enrolled in college				
		Total	Men	Women	White	Black[1]
1970	2,757	52	55	49	52	48
1975	3,186	51	53	49	51	46
1980	3,089	49	47	52	50	43
1981	3,053	54	55	53	55	43
1982	3,100	51	49	52	52	37
1983	2,964	53	52	53	55	39
1984	3,012	55	56	54	58	40
1985	2,666	58	59	57	59	42

[1] Data prior to 1977 refer to black and other workers.

Not surprisingly, dropouts also tend to come from families with lower income levels than high school graduates. For example, just 16 percent of dropouts are members of families with annual incomes of more than $30,000, compared with 31 percent of high school graduates not enrolled in college, and 56 percent of high school graduates enrolled in college.

Looking down the road at adulthood, the earnings situation can be bleak for those who do not complete high school. As shown below, median earnings for high school dropouts who work all year at full-time jobs lag behind their better-educated peers throughout their working lives.

	Age 16 to 24	*Age 25 to 64*
Total, year-round, full-time median earnings, 1984	$11,537	$20,752
Less than 4 years of high school	9,551	14,776
4 years of high school	11,331	18,350
1 to 3 years of college	11,897	21,079
4 years or more of college	16,470	27,777

The exceptionally high unemployment rates and poor earnings prognosis for dropouts suggest that a lack of liter-

[1] Labor force as a percent of population.

[2] Unemployed as a percent of labor force.

acy is a serious problem for unemployed youth. The study by the National Center for Education Statistics shows that about one-third of the the sophomores who had dropped out of high school reported their reason as poor grades, or that "school was not for me."[7]

—— *FOOTNOTES* ——

[1] Data in this report are derived primarily from information collected in the October 1985 Current Population Survey (CPS), conducted and tabulated for the Bureau of Labor Statistics by the Bureau of the Census. Most data relate to persons 16 to 24 years of age in the civilian noninstitutional population in the week ending Oct. 12, 1985. Because it is a sample survey, estimates derived from the CPS may differ from the actual counts that could be obtained from a complete census. Therefore, small estimates or small differences between estimates should be interpreted with caution. For further information on sampling reliability, see *Students, Graduates, and Dropouts, October 1980–82*, Bulletin 2192 (Bureau of Labor Statistics, 1983).

For the most recent report on this topic, see Anne McDougall Young, "Fewer students in work force as school age population declines," *Monthly Labor Review*, July 1984, pp. 34–37.

[2] Figures for recent high school graduates 16 to 24 years old and enrolled in college include only those in schools that grant academic degrees. However, there are sizable numbers of students in "special schools," offering business, health, trades, technology, and cosmetology programs, among others. The U.S. Department of Education estimates that there were 1.8 million 16- to 24-year-olds in these schools in 1982. For further information, see *Participants in Postsecondary Education: October 1982*, Bulletin 84–309 (National Center for Education Statistics, November 1984).

Foreign Labor Developments

ILO adopts asbestos standard; focuses on employment issues

TADD LINSENMAYER

The 1986 International Labor Organization (ILO) Conference agreed to new standards to protect workers from asbestos hazards and urged governments to adopt policies to reduce youth unemployment, create jobs through small enterprise development, and counteract the negative employment consequences of international debt. These standards were among the highlights of the 3-week Conference, held in Geneva, Switzerland, June 4 to 25, and attended by 1,800 delegates from 140 countries.

U.S. Secretary of Labor William E. Brock cited the nuclear disaster in Chernobyl as an example of the serious safety and health hazards which can be associated with some new technologies and called on the ILO and its members to intensify efforts to share information on such perils. Brock pledged to make greater use of the ILO's occupational health hazard alert system in developing safety and health standards for Americans.

The heart of the ILO's annual Conference is its standard-setting activities—the development of conventions, which are legally binding treaties when ratified by governments, and recommendations. In recent years, many ILO members have advocated slowing the pace in the development of new standards to allow governments time to act on those already on the books. (The ILO has adopted 162 conventions since its creation in 1919.)

The 1986 Conference adopted only two new standards: a convention and a recommendation on asbestos. The convention requires that ratifying governments develop national programs to prevent worker exposure to asbestos health hazards, including worker exposure limits and effective inspection programs. The convention prohibits the use of crocidolite—a type of asbestos considered particularly dangerous—as well as the spraying of asbestos. The question of banning other types of asbestos was left to the discretion of national governments. Special provisions deal with demolition of buildings containing asbestos, the handling and cleaning of work clothing, and environmental and medical surveillance. The asbestos recommendation covers many of these same questions in greater detail.

The Conference also considered youth unemployment and small enterprise development. Unlike asbestos, these did not lead to new standards, but rather resulted in nonbinding conclusions.

According to the U.S. Government representative, the work of the committee on youth was complicated by the efforts of some delegates to raise extraneous political issues. For example, the Soviet Union and certain Eastern European countries introduced a resolution which attempted to link youth unemployment to the arms race. While this resolution was never seriously considered, the youth committee did adopt a paragraph sponsored by its worker and employer members urging that "socially unproductive activities which pose a threat to peace should be redirected towards socially and economically productive activities . . ."

The Conference's conclusions on youth recognized that the modern sector of the economy in many countries has only a limited capacity to absorb the estimated 1 billion youth who will be in the world labor force by the year 2000—84 percent of them in developing countries. It advocated, therefore, that more resources should be focused on the creation of employment in the private sector, self-employment, and jobs for youth in the rural agricultural and nonagricultural sectors of the economy. The Conference also urged better-designed national training and educational programs that would provide "employable skills" to young jobseekers.

The Conference's conclusions on small enterprise development also dealt primarily with employment creation. The U.S. Government representative noted, for example, that two-thirds of the 43 million new jobs created in the United States since 1960 were in small businesses. The Conference called on governments to adopt policies to promote small enterprise development, including "simplifying and streamlining" government regulations which hinder the establishment of small enterprises. This latter point was qualified by an explicit recognition of the need for "fully protecting workers' rights."

To assist entrepreneurs in establishing new enterprises, the ILO's conclusions call for national small enterprise development policies which include effective management training programs, the creation of technology centers, and financial assistance programs (including credit guarantees). The Conference also encouraged the ILO to expand its own small enterprise development efforts.

Tadd Linsenmayer is director of the Office of International Organizations, Bureau of International Labor Affairs, U.S. Department of Labor.

Perhaps the most controversial issue during the Conference was a resolution on the employment implications of international debt. The worker delegates at the Conference, joined by a majority of governments, particularly from Latin America, supported adoption of a resolution calling on the ILO to become more involved in finding solutions to the debt problem. The resolution urged creditor governments to extend debt repayment schedules, reduce interest rates, and stabilize foreign exchange rates and commodity prices. It also called for a special "high-level" ILO meeting involving key government labor and finance officials, the heads of international financial organizations such as the International Monetary Fund, and worker and employer representatives. The purpose of this meeting would be to examine "the impact of international trade and financial and monetary policies on employment and poverty."

The sponsors of this resolution argued that the austerity programs required to cope with the debt crisis were leading to higher unemployment in many countries. They insisted that the ILO should work with the international financial organizations and with debtor and creditor governments to find more equitable solutions. Although the United States and most other Western governments opposed the resolution on the grounds that the ILO lacked both the responsibility and expertise to deal with international financial questions, it was adopted by a wide margin.

Almost equally controversial was the adoption, after more than 20 years of debate, of proposals to change the ILO's structure. Most of these proposals concern the ILO Governing Body, the organ responsible for budget and administrative decisionmaking. Specifically, the proposals would expand the Governing Body from 56 to 112 members and make all seats elective (presently, 10 of the 28 government seats are nonelective and reserved for the "states of chief industrial importance": United States, the Soviet Union, United Kingdom, France, Federal Republic of Germany, Italy, Japan, India, China, and Brazil. Other proposals relate to the election of the ILO's director general, the quorum needed for valid Conference votes, and procedures for considering resolutions which condemn ILO members.

The major point of controversy, according to U.S. Government Delegate Ambassador Robert W. Searby, stemmed from Soviet demands for guaranteed seats in the employer benches of the Governing Body. The employers have steadfastly refused to elect any Communist "employers" to the Governing Body, arguing that they are, in reality, agents of the government and not free employers.

According to Searby, the Soviets found themselves virtually without support for their proposal for guaranteed seats. (The majority of ILO members supported the ILO's principle of tripartism, including the autonomy of the worker and employer groups.) Unable to block final agreement on the other structural proposals, the Soviets manifested their displeasure through a series of procedural maneuvers during the opening days of the Conference which thwarted, for 5 days, the start of the campaign which began with the committees on resolutions and the application of ILO standards. The Soviet opposition to these committees stemmed from their alleged underrepresentation of Communist employers (virtually the same complaint they have with the employer benches in the Governing Body). When the structure proposals were presented for a preliminary decision near the end of the Conference, the Soviets continued their protest campaign by insisting on time-consuming votes.

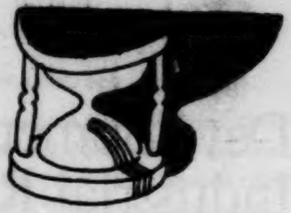
The Conference overwhelmingly approved the structure proposals as amendments to the ILO constitution and standing orders. The constitutional amendments must now be submitted to governments for ratification. None of the amendments will go into effect until they are ratified by two-thirds of the member governments, including 5 of the 10 states of chief industrial importance.

The Conference committee which deals with the application of standards—normally controversial because of its focus on significant human rights violations—was relatively quiet this year. Because of delays due to Soviet opposition to its composition, the committee considered far fewer cases than in previous years, and, according to U.S. members of the committee, considered no Soviet bloc cases. Of the three Soviet bloc cases identified for discussion by the committee, one (Poland's violation of trade union rights) could not be discussed because that government did not send a delegation to the Conference, in view of its announced withdrawal from the ILO. Two other cases (involving Nicaragua and Romania) could not be considered because those governments refused to attend the committee to discuss any of the allegations. The Soviet policy of boycotting the ILO's supervisory machinery provoked a strong reaction from the worker and employer members of the committee and from many governments, and promises to be a major issue at the 1987 Conference.

The Conference committee cited Iran for "continued failure" to eliminate discrimination against the Baha'i religious sect, and adopted "special paragraphs" expressing concern over the nonapplication of ratified conventions in Pakistan (forced labor and fee-charging employment agencies) and Bangladesh (treatment of tribal populations).

In other actions, the Conference adopted proposals to help the ILO offset budget shortfalls arising from the declining value of the dollar. (The ILO receives its income in dollars, but pays most of its bills in Swiss francs.) It also strongly urged, over U.S. Government objections, economic sanctions against South Africa as a weapon to eliminate apartheid. ☐

Major Agreements Expiring Next Month



This list of selected collective bargaining agreements expiring in November is based on information collected by the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more. Private industry is arranged in order of Standard Industrial Classification.

Industry or activity	Employer and location	Labor organization[1]	Number of workers
Private			
Food products	General Foods Corp. (Battle Creek, MI)	Retail, Wholesale and Department Store	1,350
	Tropicana Products, Inc. (Bradenton, FL)	Teamsters (Ind.)	1,350
Fabricated metal products	Olin Corp. (East Alton, IL)	Machinists	2,300
Electrical products	Gibson Products Corp. (Greenville, MI)	Auto Workers	3,500
Transportation equipment	Dana Corp., Parish Division (Reading, PA)	Steelworkers	2,200
Instruments	Leeds and Northrup Co. (North Wales, PA)	Auto Workers	1,000
Miscellaneous manufacturing	Armstrong World Industries (Lancaster, PA)	Rubber Workers	1,600
Air transportation	American Airlines (Interstate)	Association of Professional Flight Attendants (Ind.)	6,200
Utilities	Columbia Gas Transmission Corp. (Interstate)	Oil, Chemical and Atomic Workers	1,000
Retail trade	Kroger Co. (Interstate)	Food and Commercial Workers	5,700
	Century Food Stores (Milwaukee, WI)	Food and Commercial Workers	2,000
Insurance	Blue Cross-Blue Shield of Wisconsin (Milwaukee, WI)	Office and Professional Employees	1,450
Real estate	Chicago walk-up apartments (Chicago, IL)	Service Employees	4,900
	Chicago fireproof buildings (Chicago, IL)	Service Employees	2,600
Services	Textile Maintenance Institute of Chicagoland, dry cleaning contract (Chicago, IL)	Textile Processors (Ind.)	1,700
	Textile Maintenance Institute of Chicagoland, laundry, linen and industrial contract (Chicago, IL)	Textile Processors (Ind.)	1,000
	Associated Press (Interstate)	Wire Service Guild, Newspaper Guild	1,400
	RCA Corp., RCA Service Co. Division (Interstate)	Electrical Workers (IBEW)	2,500
Amusements	Phonograph Record Labor Agreement (Interstate)	Musicians	6,000
Hospitals	Johns Hopkins Hospital (Baltimore, MD)	Hospital and Health Care Employees	1,400
	Major Honolulu hospitals (Hawaii)	Nurse's Association (Ind.)	1,500
Public			
Utilities	Arizona: Phoenix Salt River Project	Electrical Workers (IBEW)	3,500
General government	Michigan: Wayne County multiunit	State, County and Municipal Employees	3,000
Transit	Illinois: Chicago Transit Authority multidepartments	Transit Union	11,000
	Pennsylvania: Allegheny County Port Authority	Transit Union	2,550

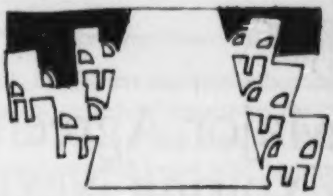
Developments in Industrial Relations



New retirement system for Federal employees

Pension eligibility requirements, financing, and benefits were significantly revised under provisions of the Federal Employees' Retirement System Act of 1986. The new system (FERS), effective January 1, 1987, will cover all Federal civilian employees hired on or after that date and virtually all earlier hires with fewer than 5 years of nonmilitary service on December 31, 1986. Since January 1, 1984, these employees have been subject to interim retirement rules under which they are covered by both the existing Civil Service Retirement System (CSRS) and the Social Security system. However, they make reduced payments to the CSRS (1.3 percent of earnings instead of the usual 7 percent) and contribute the full employee share to Social Security.

Employees currently covered by the interim retirement rules with more than 5 years of service on December 31, 1986, will continue under the dual benefit coverage unless they opt to transfer to the FERS between July 1 and December 31, 1987.

Employees covered only by CSRS will remain under that system unless they opt to shift to the FERS. Eligibility for unreduced benefits under CSRS is age 62 after 5 years of service; age 60 after 20 years of service; or age 55 after 30 years (beginning in 2003, this age requirement will be increased, in stages, to age 57 in 2025). Retirement benefits continue to be based on the employee's average annual earnings during the three highest consecutive years. The formula is 1.5 percent of the average annual earnings figure for each of the first 5 years of service, plus 1.75 percent of the earnings figure for each of the next 5 years of service, plus 2 percent of the earnings figure for each year of service in excess of 10. For 30 years of service, the result is a benefit equal to 56.25 percent of the average annual earnings figure.

The FERS consists of three benefits—Social Security, CSRS, and a thrift savings plan.

Under Social Security, employees will pay a reduced Old Age, Survivors, and Disability Insurance (OASDI) tax of 5.7 percent (6.2 percent in 1990), in addition to the medicare tax which all Federal employees pay. The OASDI and medicare taxes are applied on earnings up to a specified amount (currently $42,000).

The second benefit is the CSRS, to which employees will contribute 1.3 percent of their annual earnings, dropping to 0.94 percent in 1988 and to 0.8 percent in 1990. Age and length of service requirements are as described above for employees staying in the CSRS. The annual benefit will be calculated at 1.0 percent of a retiring employee's average annual earnings for the three highest consecutive years, multiplied by the number of years of service. If the employee is age 62 or older at retirement, the calculation factor will be 1.1 percent. If younger, the employee will receive a supplement equal to the estimated Social Security benefit that would be payable based on current Federal service under Social Security, calculated as if the employee was age 62. The supplement, which is subject to reduction if outside earnings exceed limits, will cease at age 62, when the retiree begins drawing actual Social Security benefits.

The third benefit is a thrift savings plan. It offers three types of tax deferred investments: special Government securities, fixed income securities, and a stock index fund. The Government will contribute an amount equal to 1 percent of each employee's pay to the plan, even if the employee does not participate. In addition, the Government will contribute a dollar for each employee dollar contributed up to 3 percent of pay, and 50 cents for each employee dollar up to the next 2 percent of pay. The maximum employee contribution is 10 percent of pay.

Employees who opt for coverage by CSRS only may invest up to 5 percent of their pay in the special Government securities, but the Government will not contribute matching funds.

The Federal Employees' Retirement System Act limits automatic cost-of-living adjustments payable from the CSRS fund. Annual adjustments will be the actual 12-month rise in the BLS Consumer Price Index if it is less than 2 percent, 2 percent if the rise is 2 to 3 percent, and the rise minus 1 percentage point if the rise is 3 percent or more. The adjustments apply to all retirees, beginning at age 62. Previously, the formula provided for unreduced adjustments for all retirees, regardless of age.

The new retirement system is expected to save the Government $42 million in 1987, rising to $2.67 billion a year in 1991. Major changes also were made in the retirement system for military personnel. (See *Monthly Labor Review*, September 1986, pp. 39–40.)

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

Entertainers settle, avert strike

A strike in the entertainment industry was averted when the Alliance of Motion Picture and Television Producers settled with two actors' unions in a 14-hour bargaining session. The last time members of the Screen Actors Guild and the American Federation of Television and Radio Artists struck was in 1980, when they were out for 10 weeks. This cost the industry a reported $40 million and delayed the start of the 1980 prime time television season by 2 months.

Under the 3-year contracts, the $361 minimum daily pay rate for actors was raised by 5 percent effective immediately, and by another 5 percent on January 1, 1988. In another compensation change, the actors will receive 4.5 percent of the producers' first $1 million of annual gross receipts from the sale of videocassettes, plus 5.4 percent of sales in excess of $1 million. They will also receive a $3 million lump-sum payment. Previously, they received 3.6 percent of gross receipts.

There also were improvements in pension and insurance benefits and changes in affirmative action hiring, safety procedures for stunt people, and working conditions for child actors. The contracts cover 92,000 members of the unions, of whom only a small percentage are working at a given time.

Lengthy talks between Delta, Air Line Pilots end

Thirteen months of negotiations between Delta Air Lines and the Air Line Pilots ended when the parties agreed on a 30-month contract that included a temporary two-tier pay system. A union official said Delta insisted on the two-tier system "for the perception" among its other employees, who are nonunion and are already covered by such plans, as well as for the resulting labor cost saving.

Under the system, new pilots are paid at 66 percent of the rates applicable to those hired earlier. After 5 years of service, the employees in the lower tier will move into the upper tier.

In another provision, the pilots agreed to fly 80 hours a month, a 5-hour increase. To some extent, the resulting savings will be offset by a requirement that the carrier increase the number of captains and first officers. Reportedly, Delta now has 4,200 pilots and plans to hire 50 a month for an indefinite period.

The contract also provides for cuts in paid vacation and leave time and changes in training, staffing, and hours of service which the union said will enable Delta to "compete effectively in the deregulated marketplace." In return for these changes, Delta agreed that there will be no job eliminations or downgradings stemming from the productivity improvements.

The contract, which is amendable on March 1, 1989, also provided for a 1-percent wage increase on January 1, 1988, and a 2-percent increase on January 1, 1989.

Engineers at RCA get new contract

About 2,000 professional engineers at RCA Corp. facilities in Bloomfield, Camden, and Moorestown, NJ, were covered by a 3-year contract that provided for general salary increases of 3, 3, and 2.5 percent in the respective years, and minimum merit increases of 3 percent in each year for eligible employees. Engineers who are promoted will also receive lump-sum payments of $400, $600, or $900.

The system of determining who will stay on the payroll in the event of operation cuts was modified to give engineers 9 "retention points" for completing 50 percent of the course work for a master's degree and 10 points for completing 75 percent of the requirements. Employees continue to receive 8 points for a bachelor's degree, 12 points for a master's degree, and 14 points for a Ph.D.

The union, the Association of Scientists and Professional Engineering Personnel, and RCA also adopted provisions to contain the rise in health care costs by more closely monitoring hospital stays and surgery.

Delaney to head Locomotive Engineers

Discord within the Brotherhood of Locomotive Engineers was reflected in convention delegates' selection of Robert Delaney to head the union, replacing incumbent John F. Sytsma. Delaney, who will serve for a 5-year term, prevailed by a vote of 371 to 301. The discord resulted, in part, from Delaney's assertion that Sytsma had misused union funds and had rigged the outcome of a 1985 referendum in which he narrowly averted a recall that would have ended his second 5-year term of office. The resulting legal case is now before a Federal appeals court for a decision on whether the Department of Labor or a Federal district court should rule on the validity of the referendum results.

Convention delegates also criticized the union's December 1985 settlement with the Nation's railroads, contending that Sytsma erred in accepting terms—including cuts in some types of pay and revisions in work rules—similar to those negotiated by the rival United Transportation Union. (See *Monthly Labor Review*, January 1986, pp. 7–8.)

In other actions, the delegates cut the president's salary to $100,000 a year, from $145,000. Membership in the union stands at 31,000 today, including 5,000 retirees, compared with a peak of about 100,000 in the early 1940's.

Clerks, meatcutters get lump-sum payments

In Eastern Pennsylvania, lump-sum payments were a feature of a settlement between Acme Markets and the United Food and Commercial Workers. About 2,400 clerks and meatcutters at 55 stores were covered by the 3-year accord. Each of the six semiannual payments will be calculated at 25 cents for each hour worked and each hour of paid leave during the preceding 6 months. Employees below the top scale are not eligible for the payments but they will continue to receive progression step increases, which were set at 25 cents an hour (previously, the increases varied). Prior to the settlement, pay rates ranged from $5.15 an hour for part-time clerks hired after June 22, 1980, to $10.51 for meat department heads.

The parties also agreed to raise the top scale for part-time employees to $6 an hour (from $5.15), narrowing the difference with part-timers hired earlier, who are paid $6.97. Acme also agreed to:

- Change 100 part-time workers to full time status.
- Restore to full-time status 50 employees who had been reduced to part-time status without fault.
- Raise the night work premium to 50 cents an hour from 25 cents.
- Make payments into the health and welfare fund for all hours worked. Previously, payments were made only for hours worked in excess of 90 a month.
- Raise the pension rate to $20 a month for each year of credited service, from $19, beginning January 1, 1987.

Drug store chains negotiate pattern contract

In Southern California, the United Food and Commercial Workers and three drug store chains negotiated a contract that was expected to set a pattern for independent drug stores and pharmacies operated by grocery chains in the region. The three drug store chains that settled were Thrifty Drugs, Clark Drugs, and Sav-on Drug Stores, which for the first time coordinated their bargaining with the union. The 12,000 workers covered by the settlement consisted of 10,000 clerks at the three companies and pharmacists at Thrifty and Clark. (Sav-On pharmacists are represented by the Guild for Professional Pharmacists.)

The accord for the pharmacists provided for wage increases of 85 cents an hour on July 1, 1986, and 50 cents on July 1 of 1987 and 1988 and on January 1, 1989, bringing their pay rate to $22.25 an hour. In July 1987 and January 1988, they will receive lump-sum payments based on hours worked during the preceding 6 months. The payments will be calculated at 25 cents and 50 cents an hour, respectively. Finally, the 3.5-cent bonus paid for each prescription filled in excess of 80 per shift was increased, in stages, to 10 cents.

A longtime, two-tier pay structure was eliminated by giving an immediate 21-cent-an-hour pay increase to top-scale clerks hired in 1969 or later, compared with 11 cents for those hired earlier. The result was a uniform $8.35 rate, which will be increased by 10 cents in the third year. All top-scale clerks will receive four lump-sum payments over the term, each calculated at 20 cents for each hour worked during the preceding 6 months.

Clerks below the top rate will receive only progression increases during the term and the progression schedule was stretched to 5 years for those hired after July 1, 1986, compared with the existing 20 months for those hired earlier.

Other provisions included:

- A 30-cent reduction in the employers' $1.70 an hour payment into the health and welfare fund and the return of a $6 million fund excess to the employers. The requirement that the stores provide whatever financing is needed to maintain benefits was eliminated. Instead, the stores will be subject to a possible obligation increase of up to 15 cents an hour in July of 1987 and 1988.
- A 5-cent reduction in the employers' 52.5-cent-an-hour pension fund obligation, also attributed to the healthy condition of the fund.
- Permission for vendors to stock and price merchandise as long as it does not result in the layoff of employees in the bargaining unit.
- An increase to four (formerly three) in the number of "management" employees in the store permitted to perform bargaining unit work.
- Elimination of the $1 an hour premium for Sunday work for inexperienced employees hired after July 1, 1986.

In addition, jury duty makeup pay will now be paid only to full-time employees, new hires who had worked in the industry prior to 1969 will no longer be automatically entitled to start work at top scale, and new hires will now receive pay progression credit only for work performed in the industry during the last 5 years.

Nurses' contract provides pay increases

The Washington Hospital Center and the District of Columbia Nurses Association negotiated a 27-month contract that provided for 3-percent salary increases in June and December of 1986, and 2-percent increases in June and December of 1987. In addition, each nurse will receive a regular 3.5-percent progression increase on his or her anniversary date in the second contract year. Such increases, which were made annually under the prior contract, were frozen during the first year of the new contract. The initial 3-percent wage increase brought hourly pay rates to $11.36 for newly hired registered nurses, $14.35 for those with 5 years' service, and $18.33 for those at the top of the salary scale.

Nurses who work any of five paid holidays will now receive a $50 a day bonus. The previous provision, which had applied to all nine paid holidays, continues to apply to the remaining four. Under that provision, nurses who work on a paid holiday receive another day off, instead of additional pay.

The accord continued a provision giving employees the choice of working Monday through Friday or on weekends. For weekend work, employees on the day shift receive 30 hours' pay for 24 hours' work and those on night shift receive 34 hours' pay for 24 hours' work. About one-third of the 1,200 employees in the bargaining unit work exclusively on weekends.

Other terms include extension of unpaid maternity leave to 1 year, from 6 months, with an assurance that returning nurses will regain their job or one in the same specialty; and a requirement that the hospital give the union 30 days' notice of impending layoffs and negotiate which employees will be laid off.

City workers in Detroit end strike

The city of Detroit and 7,000 members of the American Federation of State, County and Municipal Employees (AFSCME) ended a 19-day work stoppage by agreeing on a 3-year contract. The picket lines were observed by 5,000 other city employees, leaving the 1.2 million residents of the Nation's sixth largest city without bus, trash collection, and other services.

Following membership rejection of an earlier tentative settlement, the city asked a judge to order a return to work. The judge declined the request but did order the parties to resume bargaining, leading to the settlement.

The contract provides for a 5-percent wage increase and a $500 lump-sum payment in the first year, a 3-percent wage increase and $200 lump-sump payment in the second year, and a $400 lump-sum payment in the third year, which could be raised to as much as $800, depending on the city's financial condition.

A two-tier longevity pay system was eliminated by giving larger pay increases to workers in the lower tier. The city also agreed to finance a prototype day care facility and to give the union information on female employment for use in a pay equity study.

County employees subject to drug, alcohol testing

In Florida, about 10,700 employees were covered by a settlement that gives Metro-Dade County the right to test them for alcohol or drugs as part of a regular physical examination or when the county has a "reasonable suspicion" of abuse. If a test result is positive, actions would range from counseling to dismissal, depending on the circumstances and the degree of cooperation by the employee.

The 3-year contract, negotiated by the State, County and Municipal Employees, also provided for 4-percent pay increases in the second and third years.

School system adopts merit pay for teachers

Adoption of a merit pay plan for 8,300 teachers resulted from discussions between the Fairfax County, VA, school system and the Fairfax Education Association. School superintendent Robert R. Spillane said the proposal would make Fairfax County "the first school system in the nation to really step out and do some things" recommended in recent reports by national panels on education reform.

Under the first stage of the plan, to begin with the 1987–88 school year, teachers would be denied longevity pay increases if they are rated unsatisfactory by their principals.

Beginning with the 1989–90 school year, the rating system would be expanded to five levels. Teachers in the lowest level would be dismissed and those in the next or "marginal" level would receive no salary increase or only a small increase. Teachers rated in the mid or competent level would receive a full salary increase. Those in the top two levels—"skillful" and "exemplary"—with 6 years' service would be eligible to move to a "career level two" status and receive a 10-percent salary increase after a further year of evaluation. According to the union, top-rated teachers with 26 years of service could earn as much as $64,000 a year, compared with a current maximum of about $44,000.

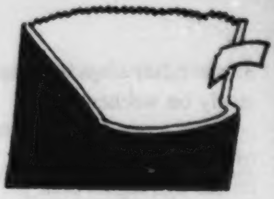
The rating of teachers would be decided by principals after consulting with two other classroom observers: a recognized outstanding teacher and a curriculum specialist. New teachers would be observed each year for the first 3 years, then once every 3 years, then every 4 years. Teachers could appeal their rating to a review board dominated by teachers.

According to Spillane, the proposal calls for substantial salary increases to ensure the cooperation of teachers in the new system. The increases average 12.1 percent effective at the beginning of the 1987–88 school year and 8.8 percent at the beginning of the 2 following years. All three amounts include usual longevity step pay increases. Implementation of the proposal was contingent on allocation of the required money by the school board in its February 1987 budget decision, and on approval by county supervisors.

Members of the union, which is an affiliate of the National Education Association, favored the proposal in a September vote and ended a work-to-rule slowdown they had begun in December 1985 to protest the size of the salary increase (4 percent) they received in July 1985.

The revamping of the teacher rating system was opposed by another union, the 900-member Fairfax County Federation of Teachers, an affiliate of the American Federation of Teachers. Rick Nelson, president of the local union, said that the proposal was unacceptable because it would give principals too much power in deciding salary raises.

Under Virginia law, the unions could only meet and confer with Spillane rather than engage in legally binding collective bargaining. Fairfax County has the Nation's 10th largest school system. □



Book Reviews

The art of conflict resolution

Techniques of Mediation. By Walter A. Maggiolo. New York, Oceana Publications, Inc., 1985. 458 pp. $45.

Walter A. Maggiolo is an acknowledged authority on conflict resolution and his book is the distillation of the experiences and techniques he used in cases spanning more than 33 years as a full-time professional mediator.

Arthur J. Goldberg, former Supreme Court Justice and Secretary of Labor, remarks in the foreword, "His book is an important text for an age which has come to recognize that conflict resolution by mediation is preferable to imposed solutions. It is must reading."

The author, building on his earlier book, *Techniques in Labor Disputes*, demonstrates the value of mediation in many areas. The major emphasis in *Techniques of Mediation* is on the practical rather than theoretical side. The book is a very successful attempt to assist mediators by describing and discussing techniques used in reaching constructive compromises.

All 32 chapters contained in this volume are written in a direct, succinct style with the practitioner always in mind. For example, chapter II is an excellent discussion of the differences between mediation and arbitration and conciliation and factfinding, as well as a description of how arbitration works, including the selection of arbitrators.

Chapter VII offers an insider's view on the history, activities, and recent changes in the Federal Mediation and Conciliation Service.

In the chapter, "Anatomy of a Mediator," the author lists 16 qualities required of a mediator. Two of these qualities struck a responsive chord—the patience of Job and the hide of a rhinoceros.

A major contribution that this book offers to the rapidly growing field of mediation is its specific treatment of topics, for example, intervention, creating doubt in the parties' minds, proposing alternate solutions, confidentiality, caucus, and aids used in reaching an agreement.

Jerome T. Barrett authored chapters on preventive mediation and ethical considerations in mediation. Barrett provides an insider's view of the Federal Mediation and Conciliation Service and an excellent review of dispute resolution in the public sector, a subject which has become critically important because of the dramatic growth of unionization among government employees.

One of the most informative chapters is the nonlabor relations use of mediation, ranging from the homeowners' warranty program to age discrimination in employment.

The appendix contains a wealth of material, including all of the major statutes, arbitration rules and regulations, and codes of professional ethics of the major mediation organizations in the United States.

The book is a treasure house of information and practical techniques on the uses of mediation and is written in a highly readable style.

Goldberg is right. This is must reading for anyone interested in mediation.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force, employment, unemployment, collective bargaining settlements, consumer, producer, and international prices, productivity, international comparisons, and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described, key definitions are given, notes on the data are set forth, and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. (Seasonally adjusted data appear in tables 1–3, 4–10, 13, 14, 17, and 18.) Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are seasonally adjusted with a procedure called X–11 ARIMA, which was developed at Statistics Canada as an extension of the standard X–11 method previously used by BLS. A detailed description of the procedure appears in *The X–11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada, Catalogue No. 12–564E, February 1980). The second change is that seasonal factors are calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at midyear for the July-December period. However, revisions of historical data continue to be made only at the end of each calendar year.

Seasonally adjusted labor force data in tables 1 and 4–10 were revised in the February 1986 issue of the *Review*, to reflect experience through 1985.

Annual revisions of the seasonally adjusted payroll data shown in tables 13, 14, and 18 were made in the July 1986 *Review* using the X–11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in table 42 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the Hourly Earnings Index in table 17—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The $2 (or any other resulting values) are described as "real," "constant," or "1967" dollars.

Additional information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule preceding these general notes. More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in *Employment and Earnings*, a monthly publication of the Bureau. More data from the household survey are published in the two-volume data book—*Labor Force Statistics Derived From the Current Population Survey*, Bulletin 2096. More data from the establishment survey appear in two data books—*Employment, Hours, and Earnings, United States*, and *Employment, Hours, and Earnings, States and Areas*, and the annual supplements to these data books. More detailed information on employee compensation and collective bargaining settlements is published in the monthly periodical, *Current Wage Developments*. More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report*, and *Producer Prices and Price Indexes*. Detailed data on all of the series in this section are provided in the *Handbook of Labor Statistics*, which is published biennally by the Bureau. BLS bulletins are issued covering productivity, injury and illness, and other data in this section. Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.
n.e.s. = not elsewhere specified.

COMPARATIVE INDICATORS
(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-to-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonagricultural payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in: consumer prices for all urban consumers; producer prices by stage of processing; and the overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data. For detailed descriptions of each data series, see BLS *Handbook of Methods*, Volumes I and II, Bulletins 2134–1 and 2134–2 (Bureau of Labor Statistics, 1982 and 1984, respectively), as well as the additional bulletins, articles, and other publications noted in the separate sections of the *Review*'s "Current Labor Statistics Notes." Historical data for many series are provided in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). Users may also wish to consult *Major Programs, Bureau of Labor Statistics*, Report 718 (Bureau of Labor Statistics, 1985).

Household survey data

Description of the series

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 59,500 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all civilians who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. Members of the Armed Forces stationed in the United States are also included in the employed total. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **overall unemployment rate** represents the number unemployed as a percent of the labor force, including the resident Armed Forces. The **civilian unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **labor force** consists of all employed or unemployed civilians plus members of the Armed Forces stationed in the United States. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons who are retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy, and members of the Armed Forces stationed in the United States. The **labor force participation rate** is the proportion of the noninstitutional population that is in the labor force. The **employment-population ratio** is total employment (including the resident Armed Forces) as a percent of the noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 4–10 are seasonally adjusted, based on the seasonal experience through December 1985.

Additional sources of information

For detailed explanations of the data, see BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 1, and for additional data, *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). A detailed description of the Current Population Survey as well as additional data are available in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*. Historical data from 1948 to 1981 are available in *Labor Force Statistics Derived from the Current Population Survey: A Databook*, Vols. I and II, Bulletin 2096 (Bureau of Labor Statistics, 1982).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Establishment survey data

Description of the series

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by more than 250,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include working supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12–17 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in the following industries: transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and

services. These groups account for about four-fifths of the total employment on private nonagricutural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index, introduced in the May 1983 *Review*, represents the percent of 185 nonagricultural industries in which employment was rising over the indicated period. One-half of the industries with unchanged employment are counted as rising. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. The diffusion index is useful for measuring the dispersion of economic gains or losses and is also an economic indicator.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1986 data, published in the July 1986 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Unadjusted data have been revised back to April 1984; seasonally adjusted data have been revised back to January 1981. These revisions were published in the *Supplement to Employment and Earnings* (Bureau of Labor Statistics, 1986). Unadjusted data from April 1985 forward, and seasonally adjusted data from January 1982 forward are subject to revision in future benchmarks.

In the establishment survey, estimates for the 2 most recent months are based on incomplete returns and are published as preliminary in the tables (13 to 16 in the *Review*). When all returns have been received, the estimates are revised and published as final in the third month of their appearance. Thus, August data are published as preliminary in October and November and as final in December. For the same reason, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Thus, second-quarter data are published as preliminary in August and September and as final in October.

Additional sources of information

Detailed data from the establishment survey are published monthly in the BLS periodical, *Employment and Earnings*. Earlier comparable unadjusted and seasonally adjusted data are published in *Employment, Hours, and Earnings, United States, 1909–84*, Bulletin 1312–12 (Bureau of Labor Statistics, 1985) and its annual supplement. For a detailed discussion of the methodology of the survey, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 2. For additional data, see *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Unemployment data by State

Description of the series

Data presented in this section are obtained from two major sources—the Current Population Survey (CPS) and the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act and the Public Works and Economic Development Act. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for 11 States—California, Florida, Illinois, Massachusetts, Michigan, New York, New Jersey, North Carolina, Ohio, Pennsylvania, and Texas—are obtained directly from the CPS, because the size of the sample is large enough to meet BLS standards of reliability. Data for the remaining 39 States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates for the 11 States are revised to new population controls. For the remaining States and the District of Columbia, data are benchmarked to annual average CPS levels.

Additional sources of information

Information on the concepts, definitions, and technical procedures used to develop labor force data for States and sub-State areas as well as additional data on sub-States are provided in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*, and the annual report, *Geographic Profile of Employment and Unemployment* (Bureau of Labor Statistics). See also *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 4.

COMPENSATION AND WAGE DATA

(Tables 1–3; 22–29)

COMPENSATION AND WAGE DATA are gathered by the Bureau from business establishments, State and local governments, labor unions, collective bargaining agreements on file with the Bureau, and secondary sources.

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It uses a fixed market basket of labor—similar in concept to the Consumer Price Index's fixed market basket of goods and services—to measure change over time in employer costs of employing labor. The index is not seasonally adjusted.

Statistical series on total compensation costs and on wages and salaries are available for private nonfarm workers excluding proprietors, the self-employed, and household workers. Both series are also available for State and local government workers and for the civilian nonfarm economy, which consists of private industry and State and local government workers combined. Federal workers are excluded.

The Employment Cost Index probability sample consists of about 2,200 private nonfarm establishments providing about 12,000 occupational observations and 700 State and local government establishments providing

3,500 occupational observations selected to represent total employment in each sector. On average, each reporting unit provides wage and compensation information on five well-specified occupations. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Fixed employment weights from the 1980 Census of Population are used each quarter to calculate the indexes for civilian, private, and State and local governments. These fixed weights, also used to derive all of the industry and occupation series indexes, ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the bargaining status, region, and metropolitan/nonmetropolitan area series, however, employment data by industry and occupation are not available from the census. Instead, the 1980 employment weights are reallocated within these series each quarter based on the current sample. Therefore, these indexes are not strictly comparable to those for the aggregate, industry, and occupation series.

Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980 to produce, when combined with the wages and salaries series, a measure of the percent change in employer costs for employee total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the *civilian* nonfarm economy (excluding Federal employees). Historical indexes (June 1981 = 100) of the quarterly rates of change are presented in the May issue of the BLS monthly periodical, *Current Wage Developments*.

Additional sources of information

For a more detailed discussion of the Employment Cost Index, see the *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 11, and the following *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor'," July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; "Estimation procedures for the Employment Cost Index," May 1982; and "Introducing new weights for the Employment Cost Index," June 1985.

Data on the ECI are also available in BLS quarterly press releases issued in the month following the reference months of March, June, September, and December; and from the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Collective bargaining settlements

Description of the series

Collective bargaining settlements data provide statistical measures of negotiated adjustments (increases, decreases, and freezes) in compensation (wage and benefit costs) and wages alone, quarterly for private industry and semiannually for State and local government. Compensation measures cover all collective bargaining situations involving 5,000 workers or more and wage measures cover all situations involving 1,000 workers or more. These data, covering private nonagricultural industries and State and local governments, are calculated using information obtained from bargaining agreements on file with the Bureau, parties to the agreements, and secondary sources, such as newspaper accounts. The data are not seasonally adjusted.

Settlement data are measured in terms of future specified adjustments: those that will occur within 12 months after contract ratification—first-year—and all adjustments that will occur over the life of the contract expressed as an average annual rate. Adjustments are worker weighted. Both first-year and over-the-life measures exclude wage changes that may occur under cost-of-living clauses that are triggered by future movements in the Consumer Price Index.

Effective wage adjustments measure all adjustments occurring in the reference period, regardless of the settlement date. Included are changes from settlements reached during the period, changes deferred from contracts negotiated in earlier periods, and changes under cost-of-living adjustment clauses. Each wage change is worker weighted. The changes are prorated over all workers under agreements during the reference period yielding the average adjustment.

Definitions

Wage rate changes are calculated by dividing newly negotiated wages by the average hourly earnings, excluding overtime, at the time the agreement is reached. Compensation changes are calculated by dividing the change in the value of the newly negotiated wage and benefit package by existing average hourly compensation, which includes the cost of previously negotiated benefits, legally required social insurance programs, and average hourly earnings.

Compensation changes are calculated by placing a value on the benefit portion of the settlements at the time they are reached. The cost estimates are based on the assumption that conditions existing at the time of settlement (for example, methods of financing pensions or composition of labor force) will remain constant. The data, therefore, are measures of negotiated changes and not of total changes in employer cost.

Contract duration runs from the effective date of the agreement to the expiration date or first wage reopening date, if applicable. Average annual percent changes over the contract term take account of the compounding of successive changes.

Notes on the data

Care should be exercised in comparing the size and nature of the settlements in State and local government with those in the private sector because of differences in bargaining practices and settlement characteristics. A principal difference is the incidence of cost-of-living adjustment (COLA) clauses which cover only about 2 percent of workers under a few local government settlements, but cover 50 percent of workers under private sector settlements. Agreements without COLA's tend to provide larger specified wage increases than those with COLA's. Another difference is that State and local government bargaining frequently excludes pension benefits which are often prescribed by law. In the private sector, in contrast, pensions are typically a bargaining issue.

Additional sources of information

For a more detailed discussion on the series, see the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 10. Comprehensive data are published in press releases issued quarterly (in January, April, July, and October) for private industry, and semi-

annually (in February and August) for State and local government. Historical data and additional detailed tabulations for the prior calendar year appear in the April issue of the BLS monthly periodical, *Current Wage Developments*.

Work stoppages

Description of the series

Data on **work stoppages** measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of time lost because of stoppage.

Data are largely from newspaper accounts and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

Additional sources of information

Data for each calendar year are reported in a BLS press release issued in the first quarter of the following year. Monthly data appear in the BLS monthly periodical, *Current Wage Developments*. Historical data appear in the *BLS Handbook of Labor Statistics*.

Other compensation data

Other BLS data on pay and benefits, not included in the Current Labor Statistics section of the *Monthly Labor Review*, appear in and consist of the following:

Industry Wage Surveys provide data for specific occupations selected to represent an industry's wage structure and the types of activities performed by its workers. The Bureau collects information on weekly work schedules, shift operations and pay differentials, paid holiday and vacation practices, and information on incidence of health, insurance, and retirement plans. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Monthly Labor Review*.

Area Wage Surveys annually provide data for selected office, clerical, professional, technical, maintenance, toolroom, powerplant, material movement, and custodial occupations common to a wide variety of industries in the areas (labor markets) surveyed. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Review*.

The National Survey of Professional, Administrative, Technical, and Clerical Pay provides detailed information annually on salary levels and distributions for the types of jobs mentioned in the survey's title in private employment. Although the definitions of the jobs surveyed reflect the duties and responsibilities in private industry, they are designed to match specific pay grades of Federal white-collar employees under the General Schedule pay system. Accordingly, this survey provides the legally required information for comparing the pay of salaried employees in the Federal civil service with pay in private industry. (See Federal Pay Comparability Act of 1970, 5 U.S.C. 5305.) Data are published in a BLS news release issued in the summer and in a bulletin each fall; summaries and analytical articles also appear in the *Review*.

Employee Benefits Survey provides nationwide information on the incidence and characteristics of employee benefit plans in medium and large establishments in the United States, excluding Alaska and Hawaii. Data are published in an annual BLS news release and bulletin, as well as in special articles appearing in the *Review*.

PRICE DATA
(Tables 2; 30–41)

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI–W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all urban consumer index (CPI–U) introduced in 1978 is representative of the 1972–73 buying habits of about 80 percent of the noninstitutional population of the United States at that time, compared with 40 percent represented in the CPI–W. In addition to wage earners and clerical workers, the CPI–U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 24,000 retail establishments and 24,000 tenants in 85 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 28 major urban centers are presented in table 31. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI–U. A rental equivalence method replaced the

asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes.

Additional sources of information

For a discussion of the general method for computing the CPI, see *BLS Handbook of Methods, Volume II, The Consumer Price Index*, Bulletin 2134–2 (Bureau of Labor Statistics, 1984). The recent change in the measurement of homeownership costs is discussed in Robert Gillingham and Walter Lane, "Changing the treatment of shelter costs for homeowners in the CPI," *Monthly Labor Review*, June 1982, pp. 9–14.

Additional detailed CPI data and regular analyses of consumer price changes are provided in the *CPI Detailed Report*, a monthly publication of the Bureau. Historical data for the overall CPI and for selected groupings may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Producer Price Indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 60,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The stage of processing structure of Producer Price Indexes organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1976, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

Notes on the data

Beginning with the January 1986 issue, the *Review* is no longer presenting tables of Producer Price Indexes for commodity groupings, special composite groups, or SIC industries. However, these data will continue to be presented in the Bureau's monthly publication *Producer Price Indexes*.

The Bureau has completed the first major stage of its comprehensive overhaul of the theory, methods, and procedures used to construct the Producer Price Indexes. Changes include the replacement of judgment sampling with probability sampling techniques; expansion to systematic coverage of the net output of virtually all industries in the mining and manufacturing sectors; a shift from a commodity to an industry orientation; the exclusion of imports from, and the inclusion of exports in, the survey universe; and the respecification of commodities priced to conform to Bureau of the Census definitions. These and other changes have been phased in gradually since 1978. The result is a system of indexes that is easier to use in conjunction with data on wages, productivity, and employment and other series that are organized in terms of the Standard Industrial Classification and the Census product class designations.

Additional sources of information

For a discussion of the methodology for computing Producer Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 7.

Additional detailed data and analyses of price changes are provided monthly in *Producer Price Indexes*. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

International price indexes

Description of the series

The BLS **International Price Program** produces quarterly export and import price indexes for nonmilitary goods traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts: it includes corporations, businesses, and individuals but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents. With publication of an all-import index in February 1983 and an all-export index in February 1984, all U.S. merchandise imports and exports now are represented in these indexes. The reference period for the indexes is 1977 = 100, unless otherwise indicated.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected quarterly by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first 2 weeks of the third month of each calendar quarter—March, June, September, and December. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined by the 4- and 5-digit level of detail of the Standard Industrial Trade Classification System (SITC). The calculation of indexes by SITC category facilitates the comparison of U.S. price trends and sector production with similar data for other countries. Detailed indexes are also computed and published on a Standard Industrial Classification (SIC-based) basis, as well as by end-use class.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. Price relatives are assigned equal importance within each weight category and are then aggregated to the SITC level. The values assigned to each weight category are based on trade value figures compiled

by the Bureau of the Census. The trade weights currently used to compute both indexes relate to 1980.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's quarterly questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

For the export price indexes, the preferred pricing basis is f.a.s. (free alongside ship) U.S. port of exportation. When firms report export prices f.o.b. (free on board), production point information is collected which enables the Bureau to calculate a shipment cost to the port of exportation. An attempt is made to collect two prices for imports. The first is the import price f.o.b. at the foreign port of exportation, which is consistent with the basis for valuation of imports in the national accounts. The second is the import price c.i.f. (cost, insurance, and freight) at the U.S. port of importation, which also includes the other costs associated with bringing the product to the U.S. border. It does not, however, include duty charges.

Additional sources of information

For a discussion of the general method of computing International Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 8.

Additional detailed data and analyses of international price developments are presented in the Bureau's quarterly publication *U.S. Import and Export Price Indexes* and in occasional *Monthly Labor Review* articles prepared by BLS analysts. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

PRODUCTIVITY DATA

(Tables 2; 42–47)

U. S. productivity and related data

Description of the series

The productivity measures relate real physical output to real input. As such, they encompass a family of measures which include single factor input measures, such as output per unit of labor input (output per hour) or output per unit of capital input, as well as measures of multifactor productivity (output per unit of labor and capital inputs combined). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the value of goods and services in constant prices produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the value of goods and services in constant dollars produced per unit of capital services input.

Multifactor productivity is the ratio output per unit of labor and capital inputs combined. Changes in this measure reflect changes in a number of factors which affect the production process such as changes in technology, shifts in the composition of the labor force, changes in capacity utilization, research and development, skill and efforts of the work force, management, and so forth. Changes in the output per hour measures reflect the impact of these factors as well as the substitution of capital for labor.

Compensation per hour is the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, and the wages, salaries, and supplementary payments for the self-employed (except for nonfinancial corporations in which there are no self-employed)—the sum divided by hours paid for. **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current dollar value of output and dividing by output. **Unit nonlabor costs** contain all the components of unit nonlabor payments *except* unit profits.

Unit profits include corporate profits and the value of inventory adjustments per unit of output.

Hours of all persons are the total hours paid of payroll workers, self-employed persons, and unpaid family workers.

Capital services is the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Labor and capital inputs combined are derived by combining changes in labor and capital inputs with weights which represent each component's share of total output. The indexes for capital services and combined units of labor and capital are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Output measures for the business sector and the nonfarm businesss sector exclude the constant dollar value of owner-occupied housing, rest of world, households and institutions, and general government output from the constant dollar value of gross national product. The measures are derived from data supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are developed from data of the Bureau of Labor Statistics and the Bureau of Economic Analysis.

The productivity and associated cost measures in tables 42–44 describe the relationship between output in real terms and the labor time and capital services involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input. Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; capital investment; level of output; utilization of capacity, energy, and materials; the organization of production; managerial skill; and the characteristics and efforts of the work force.

Additional sources of information

Descriptions of methodology underlying the measurement of output per hour and multifactor productivity are found in the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 13. Historical data for selected industries are provided in the Bureau's *Handbook of Labor Statistics*, 1985, Bulletin 2217.

INTERNATIONAL COMPARISONS

(Tables 45–47)

Labor force and unemployment

Description of the series

Tables 45 and 46 present comparative measures of the labor force, employment, and unemployment—approximating U.S. concepts—for the United States, Canada, Australia, Japan, and six European countries. The unemployment statistics (and, to a lesser extent, employment statistics) published by other industrial countries are not, in most cases, comparable to U.S. unemployment statistics. Therefore, the Bureau adjusts the figures for selected countries, where necessary, for all known major definitional differences. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country.

Definitions

For the principal U.S. definitions of the **labor force**, **employment**, and **unemployment**, see the Notes section on EMPLOYMENT DATA: Household Survey Data.

Notes on the data

The adjusted statistics have been adapted to the age at which compulsory schooling ends in each country, rather than to the U.S. standard of 16 years of age and over. Therefore, the adjusted statistics relate to the population age 16 and over in France, Sweden, and from 1973 onward, Great Britain; 15 and over in Canada, Australia, Japan, Germany, the Netherlands, and prior to 1973, Great Britain; and 14 and over in Italy. The institutional population is included in the denominator of the labor force participation rates and employment-population ratios for Japan and Germany; it is excluded for the United States and the other countries.

In the U.S. labor force survey, persons on layoff who are awaiting recall to their job are classified as unemployed. European and Japanese layoff practices are quite different in nature from those in the United States; therefore, strict application of the U.S. definition has not been made on this point. For further information, see *Monthly Labor Review*, December 1981, pp. 8–11.

The figures for one or more recent years for France, Germany, Great Britain, Italy, and the Netherlands are calculated using adjustment factors based on labor force surveys for earlier years and are considered preliminary. The recent-year measures for these countries are, therefore, subject to revision whenever data from more current labor force surveys become available.

Additional sources of information

For further information, see *International Comparisons of Unemployment*, Bulletin 1979 (Bureau of Labor Statistics, 1978), Appendix B and unpublished Supplements to Appendix B available on request. The statistics are also analyzed periodically in the *Monthly Labor Review*. Additional historical data, generally beginning with 1959, are published in the *Handbook of Labor Statistics* and are available in unpublished statistical supplements to Bulletin 1979.

Manufacturing productivity and labor costs

Description of the series

Table 47 presents comparative measures of manufacturing labor productivity, hourly compensation costs, and unit labor costs for the United States, Canada, Japan, and nine European countries. These measures are limited to trend comparisons—that is, intercountry series of changes over time—rather than level comparisons because reliable international comparisons of the levels of manufacturing output are unavailable.

Definitions

Output is constant value output (value added), generally taken from the national accounts of each country. While the national accounting methods for measuring real output differ considerably among the 12 countries, the use of different procedures does not, in itself, connote lack of comparability—rather, it reflects differences among countries in the availability and reliability of underlying data series.

Hours refer to all employed persons including the self-employed in the United States and Canada; to all wage and salary employees in the other countries. The U.S. hours measure is hours paid; the hours measures for the other countries are hours worked.

Compensation (labor cost) includes all payments in cash or kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. In addition, for some countries, compensation is adjusted for other significant taxes on payrolls or employment (or reduced to reflect subsidies), even if they are not for the direct benefit of workers, because such taxes are regarded as labor costs. However, compensation does not include all items of labor cost. The costs of recruitment, employee training, and plant facilities and services—such as cafeterias and medical clinics—are not covered because data are not available for most countries. Self-employed workers are included in the U.S. and Canadian compensation figures by assuming that their hourly compensation is equal to the average for wage and salary employees.

Notes on the data

For most of the countries, the measures refer to total manufacturing as defined by the International Standard Industrial Classification. However, the measures for France (beginning 1959), Italy (beginning 1970), and the United Kingdom (beginning 1976), refer to manufacturing and mining less energy-related products and the figures for the Netherlands exclude petroleum refining from 1969 to 1976. For all countries, manufacturing includes the activities of government enterprises.

The figures for one or more recent years are generally based on current indicators of manufacturing output, employment, hours, and hourly compensation and are considered preliminary until the national accounts and other statistics used for the long-term measures become available.

Additional sources of information

For additional information, see the *BLS Handbook of Methods*, Bulletin 2134, Vol. 1, Chapter 16 (Bureau of Labor Statistics, 1982) and periodic *Monthly Labor Review* articles. Historical data are provided in the Bureau's *Handbook of Labor Statistics*, Bulletin 2217, 1985. The statistics are issued twice per year—in a news release (generally in May) and in a *Monthly Labor Review* article (generally in December).

OCCUPATIONAL INJURY AND ILLNESS DATA

(Table 48)

Description of the series

The Annual Survey of Occupational Injuries and Illnesses is designed to collect data on injuries and illnesses based on records which employers in the following industries maintain under the Occupational Safety and Health Act of 1970: agriculture, forestry, and fishing; oil and gas extraction; construction; manufacturing; transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. Excluded from the survey are self-employed individuals, farmers with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies.

Because the survey is a Federal–State cooperative program and the data must meet the needs of participating State agencies, an independent sample is selected for each State. The sample is selected to represent all private industries in the States and territories. The sample size for the survey is dependent upon (1) the characteristics for which estimates are needed; (2) the industries for which estimates are desired; (3) the characteristics of the population being sampled; (4) the target reliability of the estimates; and (5) the survey design employed.

While there are many characteristics upon which the sample design could be based, the total recorded case incidence rate is used because it is one of the most important characteristics and the least variable; therefore, it requires the smallest sample size.

The survey is based on stratified random sampling with a Neyman allocation and a ratio estimator. The characteristics used to stratify the establishments are the Standard Industrial Classification (SIC) code and size of employment.

Definitions

Recordable occupational injuries and illnesses are: (1) occupational deaths, regardless of the time between injury and death, or the length of the illness; or (2) nonfatal occupational illnesses; or (3) nonfatal occupational injuries which involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment (other than first aid).

Occupational injury is any injury such as a cut, fracture, sprain, amputation, and so forth, which results from a work accident or from exposure involving a single incident in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to environmental factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday cases are cases which involve days away from work, or days of restricted work activity, or both.

Lost workday cases involving restricted work activity are those cases which result in restricted work activity only.

Lost workdays away from work are the number of workdays (consecutive or not) on which the employee would have worked but could not because of occupational injury or illness.

Lost workdays—restricted work activity are the number of workdays (consecutive or not) on which, because of injury or illness: (1) the employee was assigned to another job on a temporary basis; or (2) the employee worked at a permanent job less than full time; or (3) the employee worked at a permanently assigned job but could not perform all duties normally connected with it.

The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked even though able to work.

Incidence rates represent the number of injuries and/or illnesses or lost workdays per 100 full-time workers.

Notes on the data

Estimates are made for industries and employment-size classes and for severity classification: fatalities, lost workday cases, and nonfatal cases without lost workdays. Lost workday cases are separated into those where the employee would have worked but could not and those in which work activity was restricted. Estimates of the number of cases and the number of days lost are made for both categories.

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses, or lost workdays, per 100 full-time employees. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Only a few of the available measures are included in the *Handbook of Labor Statistics*. Full detail is presented in the annual bulletin, *Occupational Injuries and Illnesses in the United States, by Industry*.

Comparable data for individual States are available from the BLS Office of Occupational Safety and Health Statistics.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration, respectively. Data from these organizations are included in BLS and State publications. Federal employee experience is compiled and published by the Occupational Safety and Health Administration. Data on State and local government employees are collected by about half of the States and territories; these data are not compiled nationally.

Additional sources of information

The Supplementary Data System provides detailed information describing various factors associated with work-related injuries and illnesses. These data are obtained from information reported by *employers* to State workers' compensation agencies. The Work Injury Report program examines selected types of accidents through an employee survey which focuses on the circumstances surrounding the injury. These data are not included in the *Handbook of Labor Statistics* but are available from the BLS Office of Occupational Safety and Health Statistics.

The definitions of occupational injuries and illnesses and lost workdays are from *Recordkeeping Requirements under the Occupational Safety and Health Act of 1970*. For additional data, see *Occupational Injuries and Illnesses in the United States, by Industry*, annual Bureau of Labor Statistics bulletin; BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 17; *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985), pp. 411–14; annual reports in the *Monthly Labor Review*; and annual U.S. Department of Labor press releases.

1. Labor market indicators

Selected indicators	1984	1985	1984		1985				198
			III	IV	I	II	III	IV	I
Employment data									
Employment status of the civilian noninstitutionalized population (household survey)[1]

---

[1] Cost (cents-per-hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.

[2] Consist of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

[3] Consists of legislative, judicial, administrative, and regulatory activities.

[4] Includes, for example, library, social, and health services.

NOTE: Beginning June 1986, ECI jobs are classified according to definitions used in the 1980 census. Prior to June 1986, they were classified according to the 1970 census. Differences between the two classification systems are slight, as indicated in "Introducing new weights for the Employment Cost Index," *Monthly Labor Review*, June 1985.

23. Employment Cost Index, wages and salaries, by occupation and industry group

(June 1981 = 100)

[1] The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the *Monthly Labor Review* Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.

NOTE: Beginning June 1986, ECI measures are based on fixed employment counts from the 1980 Census of Population, rather than from the 1970 census.

25. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Quarterly average							
	1984	1985	1984		1985				1986	
			III	IV	I	II	III	IV	I	II
Specified adjustments:										
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:										
First year of contract	3.6	2.6	2.7	3.7	3.6	3.5	2.0	2.0	0.4	0.7
Annual rate over life of contract	2.8	2.7	3.1	2.9	2.7	3.4	3.0	1.4	1.3	1.6
Wage adjustments, settlements covering 1,000 workers or more:										
First year of contract	2.4	2.3	2.1	2.3	3.3	2.5	2.0	2.1	1.0	1.3
Annual rate over life of contract	2.4	2.7	2.6	1.5	3.2	2.8	3.1	1.9	1.6	2.0
Effective adjustments:										
Total effective wage adjustment [3]	3.7	3.3	1.2	.7	.7	.8	1.2	.5	.6	.7
From settlements reached in period	.8	.7	.2	.3	.1	.2	.2	.1	.0	.2
Deferred from settlements reached in earlier periods	2.0	1.8	.7	.2	.6	.5	.5	.2	.4	.6
From cost-of-living-adjustments clauses	.9	.7	.3	.2	.1	.1	.4	.1	.2	.0

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

p = preliminary.

26. Average specified compensation and wage adjustments, major collective bargaining settlements in private industry situations covering 1,000 workers or more during 4-quarter periods (in percent)

Measure	Average for four quarters ending--							
	1984		1985				1986	
	III	IV	I	II	III	IV	I	II
Specified total compensation adjustments, settlements covering 5,000 workers or more, all industries:

[1] Data do not meet publication standards.

p = preliminary.

27. Average effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more during 4-quarter periods (in percent)

Effective wage adjustment	Average for four quarters ending–						
	1984	1985				1986	
	IV	I	II	III	IV	I	II^p
For all workers:[1]							
Total	3.7	3.6	3.5	3.5	3.3	3.1	2.9
From settlements reached in period	.8	.7	.9	.9	.7	.6	.5
Deferred from settlements reached in earlier period	2.0	2.2	1.9	1.8	1.8	1.7	1.8
From cost-of-living-adjustments clauses	.9	.7	.7	.8	.7	.8	.7
For workers receiving changes:							
Total	4.4	4.5	4.2	4.3	4.1	4.0	3.8
From settlements reached in period	3.0	2.9	2.9	2.8	3.4	2.9	2.5
Deferred from settlements reached in earlier period	4.0	4.2	3.9	3.7	3.7	3.5	3.4
From cost-of-living-adjustments clauses	2.7	2.3	2.3	2.8	2.2	2.5	2.1

[1] Because of rounding total may not equal sum of parts.

p = preliminary.

28. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, State and local government collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		First 6 months 1986^p
	1984	1985	
Specified adjustments:			
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:			
First year of contract	5.2	4.2	6.7
Annual rate over life of contract	5.4	5.1	6.4
Wage adjustments, settlements covering 1,000 workers or more:			
First year of contract	4.8	4.6	6.1
Annual rate over life of contract	5.1	5.4	6.0
Effective adjustments:			
Total effective wage adjustment [3]	5.0	5.7	1.8
From settlements reached in period	1.9	4.1	0.6
Deferred from settlements reached in earlier periods	3.1	1.6	1.2
From cost-of-living-adjustment clauses	([4])	([4])	(4)

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

[4] Less than 0.05 percent.

p = preliminary.

29. Work stoppages involving 1,000 workers or more

Measure	Annual totals		1985					1986							
	1984	1985	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.^p	Feb.^p	Mar.^p	Apr.^p	May^p	June^p	July^p	Aug.^p
Number of stoppages:															
Beginning in period	62	54	6	11	6	3	2	4	3	2	3	5	10	10	8
In effect during period	68	61	18	20	20	13	9	7	7	8	8	10	15	20	19
Workers involved:															
Beginning in period (in thousands)	376.0	323.9	15.3	69.5	76.6	26.2	8.2	7.6	24.0	11.2	6.1	28.6	198.0	40.9	110.7
In effect during period (in thousands)	391.0	584.1	66.8	93.9	119.3	47.0	38.0	12.0	28.4	36.6	17.6	41.2	205.9	57.1	131.1
Days idle:															
Number (in thousands)	8,499.0	7,079.0	810.8	863.8	1,428.8	688.2	661.9	170.0	309.5	387.5	297.3	303.6	3,684.3	831.6	1,514.3
Percent of estimated working time[1]	.04	.03	.04	.04	.06	.04	.03	.01	.02	.02	.02	.02	.07	.04	.07

[1] Agricultural and government employees are included in the total employed and total working time: private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in "'Total economy' measure of strike idleness," *Monthly Labor Review*, October 1968, pp. 54-56.

p = preliminary

30. Consumer Price Index for All Urban Consumers: U.S. city average, by expenditure category and commodity or service group; and CPI for Urban Wage Earners and Clerical Workers, all items

[1] Area is generally the Standard Metropolitan Statistical Area (SMSA), exclusive of farms. L.A.-Long Beach, Anaheim, Calif. is a combination of two SMSA's, and N.Y., N.Y.-Northeastern N.J. and Chicago, Ill.-Northwestern Ind. are the more extensive Standard Consolidated Areas. Area definitions are those established by the Office of Management and Budget in 1973, except for Denver-Boulder, Colo. which does not include Douglas County. Definitions do not include revisions made since 1973.

[2] Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:

M - Every month.
1 - January, March, May, July, September, and November.
2 - February, April, June, August, October, and December.

[3] Regions are defined as the four Census regions.

The population size classes are aggregations of areas which have urban population as defined:

A-1 - More than 4,000,000.
A-2 - 1,250,000 to 4,000,000.
B - 385,000 to 1,250,000
C - 75,000 to 385,000.
D - Less than 75,000.

Population size class A is the aggregation of population size classes A-1 and A-2.

- Data not available.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Because each local index is a small subset of the national index, it has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error than the national index. As a result, local area indexes show greater volatility than the national index, although their long-term trends are quite similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in escalator clauses.

Sweden	3.1	2.8	3.0	3.0	2.9	2.8	2.7	2.8	2.6

[1] Quarterly rates are for the first month of the quarter.

[2] Major changes in the Italian labor force survey, introduced in 1977, resulted in a large increase in persons enumerated as unemployed. However, many persons reported that they had not actively sought work in the past 30 days, and they have been provisionally excluded for comparability with U.S. concepts. Inclusion of such persons would more than double the Italian unemployment rate shown.

- Data not available.

NOTE: Quarterly figures for France, Germany, and Great Britain are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures.

46. Annual data: Employment status of the civilian working-age population, ten countries

---

[1] Total cases include fatalities.

[2] The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as:
(N/EH) X 200,000, where:
N = number of injuries and illnesses or lost workdays.
EH = total hours worked by all employees during calendar year.
200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year.)

[3] Excludes farms with fewer than 11 employees since 1976.

NEW FROM BLS

SALES PUBLICATIONS

BLS Bulletins

Employee Benefits in Medium and Large Firms, 1985. Bulletin 2262, 91 pp. (GPO Stock No. 029-001-02903-9.) $4.75.

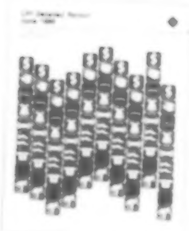
BLS Periodical Prices Reduced

BLS periodicals provide timely information on employment, occupations, wages, and prices. Subscriptions now are available at greatly reduced prices. In addition, newly available 2-year subscriptions guarantee the low prices for the next 2 years.

Monthly Labor Review
the oldest and most authoritative Government research journal in economics and social sciences. Regular features include current labor statistics and developments in industrial relations.
$16
$24 a year

Current Wage Developments
reports monthly on specific wage and benefit changes from collective bargaining agreements. Includes data on strikes or lockouts, major agreements expiring, and compensation changes.
$12
$21 a year

Occupational Outlook Quarterly
helps students and guidance counselors learn about new occupations, training opportunities, salary trends, and career counseling programs. Written in nontechnical language and illustrated in color.
$5
$11 a year



CPI Detailed Report
is the most comprehensive report on monthly consumer price indexes and rates of change.
$16
$25 a year

Employment and Earnings
gives current monthly employment and earnings statistics for the Nation as a whole, for States and for more than 200 areas. Included are household and establishment data seasonally and not seasonally adjusted. Includes annual supplement.
$22
$31 a year

Producer Prices and Price Indexes
includes monthly price movements of both farm and industrial commodities, by industry and stage of processing. Includes annual supplement.
$21
$29 a year

MONTHLY LABOR REVIEW
U.S. Department of Labor
Bureau of Labor Statistics
November 1986

In this issue:
A Special Section on Time Spent at Work

NEWARK PUBLIC LIBRARY
U.S. DOCUMENTS
DEC - 8

2.6:

U.S. DEPARTMENT OF LABOR
William E. Brock, ***Secretary***

BUREAU OF LABOR STATISTICS
Janet L. Norwood, *Commissioner*

The Monthly Labor Review is published by the Bureau of Labor Statistics of the U.S. Department of Labor. Communications on editorial matters should be addressed to the Editor-in-Chief, Monthly Labor Review, Bureau of Labor Statistics,
Washington, DC 20212.
Phone: (202) 523-1327.

Subscription price per year—$16 domestic; $20 foreign. Single copy $4.75 domestic; $5.94 foreign. Subscription prices and distribution policies for the Monthly Labor Review (ISSN 0098-1818) and other Government publications are set by the Government Printing Office, an agency of the U.S. Congress. Send correspondence on circulation and subscription matters (including address changes) to:
Superintendent of Documents,
Government Printing Office,
Washington, DC 20402

Make checks payable to Superintendent of Documents.

The Secretary of Labor has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Second-class postage paid at Washington, DC, and at additional mailing addresses.

November cover:

"Cape Cod Morning," a 1950 oil painting by Edward Hopper (1882-1967). Photography courtesy of the National Museum of American Art (The Sara Roby Collection), Washington, D.C.

Cover design by Melvin B. Moxley

MONTHLY LABOR REVIEW

NOVEMBER 1986
VOLUME 109, NUMBER 11

Henry Lowenstern, Editor-in-Chief
Robert W. Fisher, Executive Editor

A SPECIAL SECTION ON THE TIME WE SPEND WORKING

Paul O. Flaim 3 **Work schedules of Americans: an overview of new findings**
A group of articles examines data from a special 1985 household survey which includes information on the number of workers who moonlight, work at home, or have flexible hours

Shirley J. Smith 7 **The growing diversity of work schedules**
While the 40-hour, 5-day workweek remains the schedule of choice, extended and compressed work schemes are becoming more popular

Earl F. Mellor 14 **Shift work and flexitime: how prevalent are they?**
Shift work and flexitime are not widespread; only 1 of 10 full-time workers is on an evening or night shift, and only 1 of 8 has a flexible schedule

John F. Stinson, Jr. 22 **Moonlighting by women jumped to record highs**
A small proportion of workers have two jobs or more; for most, the motivation is financial, but moonlighting also provides an opportunity to explore new careers

Bruce W. Klein 26 **Missed work and lost hours, May 1985**
Absences were lower in 1985 than at any time since 1973; for the first time, service-producing industries had higher rates than goods-producing industries

Francis W. Horvath 31 **Work at home: new findings from the Current Population Survey**
More than 8 million reported at least 8 hours of home-base work in 1985; most common were services, ranging from consulting to child care

Darrell E. Carr 36 **Overtime work: an expanded view**
Survey now includes workers whose hours do not exceed the traditional 40- hour week; 1.6 million of these workers received premium pay for working overtime during 1985

Susan E. Shank 40 **Preferred hours of work and corresponding earnings**
Most workers are satisfied with the number of hours they currently work; very few would be willing to trade income for leisure time

Wayne J. Howe 45 **Temporary help workers: who they are, what jobs they hold**
Temporary help workers are disproportionately female, young, and black; they are more likely to work part time and in clerical and industrial help jobs

Labor Month In Review

SIC Revision. The Federal Office of Management and Budget announced that the Standard Industrial Classification system, which underlies all establishment-based economic statistics, is being revised, effective January 1, 1987. Here are excerpts from the OMB announcement, which appeared in the *Federal Register* for October 1, 1986, pages 35170 to 35188.

Background. The SIC system is revised periodically to reflect the economy's changing industrial composition and organization. Changes in the economy since the last major revision in 1972 require an updating of the standard. The revised SIC provides a more current classification structure with which to collect, disseminate, and analyze data on the industrial makeup of the U. S. economy. [Although the revision is effective January 1, 1987, full implementation of the new SIC will occur over several years, with some programs introducing the changes as early as 1988. Data series for years prior to implementation may not always be revised to reflect the 1987 SIC revision.]

Changes. The 1987 SIC revision has resulted in a net increase of 19 industries for Services (Division I), 8 for Wholesale Trade, and 7 for Manufacturing, with a net decrease of 34 for the other SIC Divisions. Deleted industries were merged into other industries and new industries were created by subdividing or restructuring existing industries. Various industries are also changed by transfers of individual activities, primarily to increase data classification accuracy, consistency, and usefulness, or by renumbering to change the existing three-digit structure.

Most of the industries that are deleted no longer meet the economic significance criteria for continued recognition as a separate industry. However, a few are dropped because the number of companies represented by the establishments classified in the industry is now so small as to cause disclosure problems in publishing data or because the distinctions required cause difficulties in classification.

The revision process included a comprehensive review of Transportation (Major Groups 40-47), Communications (Major Group 48), and Finance (Major Groups 60-62, and 67) to identify revisions needed due to changes in technology and government regulation. Major revisions occurred in Water Transportation, now divided by freight and passengers, and in the structure and detail of Banking and Other Credit Agencies (Major Groups 60-61), in particular to recognize changes in depository regulations. In addition, the decisions include the recognition of new industries for Cable and Other Pay Television (from 4833 and 4899) and Radiotelephone Communications Services (from 4811).

The growth of computer-related activities has resulted in a number of new industries. Several new industries are recognized for computers and computer peripheral equipment in Manufacturing (from 3573). There are industries for the sale of Computers and Computer Peripheral Equipment and Software in Wholesale Trade (from 5081) and Retail Trade (from 5732). Computer establishments are classified in Wholesale Trade if they sell primarily for business or government use and in Retail Trade if they sell primarily for household use. Additional detail is also added for computer services within current Group 737, including a separate industry for Prepackaged Computer Software.

Considerable emphasis was placed on improved detail for Services (Division I). There is a new Major Group 87 for selected professional and technical services, comprising elements of the current Business Services (Major Group 73) and Miscellaneous Services (Major Group 89). A number of changes are incorporated for Major Group 80, Health Services, to improve detail and data accuracy for this area of rapid growth. Other changes include the recognition of industries for Physical Fitness Facilities (from 7299, 7997, and 7999), Tax Return Preparation Services (from 7299) and Video Tape Rental (from 7394). Various other industries are also subdivided (for example, 7321, 7393, and 7539).

Subdivisions were created for some of the largest and fastest growing current industries in Manufacturing, including Miscellaneous Plastics Products (3079), Radio and Television Communications Equipment (3662), and Electronic Components, not elsewhere classified (3679).

SIC Manual. Clothbound copies of the "Standard Industrial Classification Manual 1987" may be ordered from the National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22161, $24 before December 31, 1986, $30 thereafter. The manual is also available on computer tape, $175, and on diskettes upon request. For telephone orders, call (703) 487-4650.□

Work schedules of Americans: an overview of new findings

A group of eight articles examines data from a special 1985 household survey covering topics such as the number of workers who moonlight, who work at home, who have flexible hours, or who would prefer to work more or fewer hours per week

Paul O. Flaim

In recent years, we have become familiar with such "megatrends" in the labor force as the rapidly increasing participation of women, the tendency toward earlier retirement among men, the maturing of the baby-boom cohorts, and the shift of workers out of the stagnant goods-producing sector of the economy and into the expanding services sector. Yet, we still have little data about the day-to-day and week-to-week working lives of American men and women. Among the most conspicuous gaps in our knowledge have been such unanswered (or only occasionally answered) questions as: How many Americans work at two jobs? How many work at night, or schedules other than the stereotypical daylight shifts? How many Americans work on weekends? How many have jobs entailing home-based work? And what proportions—if offered such a choice—would prefer to work either more or fewer hours per week at their current rates of pay?

Until recently, there was either no information at all concerning these questions or, at best, information which had been collected sporadically and which had become rather dated. Now, thanks to a special survey conducted in 1985, we have both up-to-date information with which to address some of the traditional questions on work schedules, as well as entirely new information on work-schedule topics that had not previously been studied at the national level. The new information was collected in May 1985 through a special supplement to the Current Population Survey (CPS), the monthly survey which provides the basic measurements of the labor force and unemployment for the Nation. The new findings are discussed in detail, on a topic-by-topic basis, in the eight articles which follow. Here are some selected highlights.

- Multiple jobholders—persons working at more than one job—numbered about 5.7 million in May 1985. They accounted for 5.4 percent of all employed persons, up from 4.9 percent in 1980.
- Saturday work was the usual routine for one-fourth of all workers, while 1 in 8 reported they usually worked on Sunday.
- Work outside the typical daylight hours—usually in the evening—was the usual routine for about one-sixth of the full-time workers and one-half of the part-time workers.
- Home-based work of at least 8 hours a week was reported by over 8 million workers. However, most were full-time employees who did only a small part of their work at home.
- Flexitime or other schedules enabling workers to vary the start and end of their workday was available to about 12 percent of the wage and salary workers with full-time jobs.

Paul O. Flaim is chief of the Division of Data Development and Users' Services, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

- A preference for a longer workweek (and thus "more money") was expressed by about one-fourth of the workers. In contrast, fewer than 1 in 10 said they would opt for a cut in hours accompanied by a reduction in earnings.

These and other findings from the May 1985 survey—analyzed in great detail in the articles which follow—add considerably to our knowledge of the work routines and preferences of American workers. But before we focus our attention on these detailed findings, it may be worthwhile to briefly review those historical trends in the labor force which provide a useful background and help to set the stage for the study of these topics.

Background data

While addressing few of the specific questions highlighted above, the data regularly available from the CPS already tell us a lot about the basic trends in the labor force behavior and work patterns of Americans. Through these data, we can, for example, track the historical changes in the rate of labor force participation and in the length of the workweek for the principal population groups. We also have been able to estimate—at least in a rough way—how many persons flow into and out of the labor force over a given period and thus get a notion of the dynamics of the labor force. And when we add to the regularly available data those which have been obtained from time to time through special supplements to the CPS, we can gain yet further insights into the basic labor force behavior of Americans and their work/leisure choices. Let us look briefly at some of these background data.

The expanding labor market role of American women—which can actually be tracked on a month-by-month or year-by-year basis with the data from the CPS—can be illustrated here with some key numbers for 1965 and 1985. Over this 20-year period, the labor force participation rate for women (the proportion 16 years and over who are in the labor force) climbed from 39 to 55 percent. Over the same two decades, the comparable rate for men edged down gradually from 81 to 76 percent, reflecting primarily a tendency among them to retire at an earlier age.

It is also important to note that women did not achieve their spectacular increases in labor market penetration over this 20-year period by taking mostly part-time jobs. To the contrary, the proportion of women working full-time held fairly steady—at nearly 75 percent—during this entire period.

A different perspective on the divergent trends in the work patterns of American men and women comes to us from the "work experience" data collected each March. These data show what proportion of men and women did at least some work during the previous year and, among those with some employment, what proportion managed to work the entire year on a full-time basis.[1]

Focusing again on the changes between 1965 and 1985, we find that the proportion of women with at least some employment in these 2 years was respectively, 49 and 59 percent. And among the increasing number of women with some employment, the proportion actually working year round on a full-time basis posted an equally robust increase. It expanded from 39 percent in 1965 to 48 percent in 1985. This means that practically half of the women with any labor market involvement are now working full time over the entire year.

Further knowledge of the basic work patterns of Americans, particularly with regard to the dynamics of their labor force behavior, can be gained through the data obtained regularly from those not in the labor force. Because these data tell us how many of these persons left their jobs during the previous 12 months, they can be used to determine, by inference, how many entered the job market over the same period. In this regard, the data collected during 1985 show that, on average, 9.1 million of the persons outside the labor force had left the employment ranks over the previous 12 months.[2] Because there had been a net employment increase of 2.1 million, we can estimate that at least 11 million persons had to enter the job market over this period to replace the outgoing workers and to account for the additional growth.

The monthly data on "gross flows," although subject to considerable bias and seldom used, point to even larger movements into and out of the labor force. They suggest, in fact, that several million persons may enter and leave the labor force each month.[3]

While this may leave us with the impression that labor mobility is widespread in the United States, that is not necessarily the case. In fact, there is evidence that the American labor force has a large core of workers who remain in their jobs, with most of the mobility occurring among other workers, especially youths. For example, the most recent CPS data on job tenure, collected in January 1983, show that among workers 25 and older (men and women combined), 1 in 3 had been with the same employer for 10 years or more and 1 in 8 had been with the same employer for 20 years or more.[4] Here is the percent distribution of these workers by years of continuous employment with current employer:

	Total	*1 year or less*	*2 to 9 years*	*10 to 19 years*	*20 years or more*
Total	100.00	20.3	45.9	21.4	12.3
Men	100.00	18.0	42.2	23.2	16.7
Women	100.00	23.4	50.8	19.1	6.7

While the above data show women to be somewhat more concentrated in the lower tenure categories than are men, they also show that, even among women, more than one-fourth had been working continuously for the same employer for 10 years or more. It was from an analysis of these tenure data that some have concluded that, contrary to the conventional wisdom, lifetime jobs are not that uncommon for American workers.[5]

And how many years, altogether, can American workers expect to spend in the labor force over their lifetime? The answers to this question come to us in the form of "worklife" estimates, currently based on the observed labor force behavior over the course of a year of men and women at all specific ages. It has been estimated from these observations (also derived from the CPS) that a man age 25 may expect to work an additional 34 years, and that a working woman of the same age may expect to be in the labor force an additional 25 years.[6]

After this brief review of the basic patterns in the working life of Americans, as reflected in various series of data from the CPS, let us now turn back to the various analyses of the May 1985 data on the day-to-day and week-to-week routines of these workers.

Analyzing the May 1985 data

The broad picture which emerges from the various analyses of the May 1985 data is of workers with a generally strong attachment to their jobs. The great majority worked 40 hours a week, but many said they regularly worked well over that standard. As already noted, nearly 6 million held two jobs, an even larger number said they usually did some work at home, and weekend work, particularly on Saturday, was a fairly common occurrence. While most workers seemed satisfied with the length of their workweeks, the vast majority of those who would have opted for a change said that they would have preferred a longer workweek so they could earn more money. As a further indication of the relatively strong attachment to their jobs, fewer than 5 percent of the full-time workers reported an absence from work in the week preceding this special survey.

Of the articles that follow, Shirley J. Smith highlights the predominance of the 5-day 40-hour workweek. Although finding little change in recent years in the proportion of workers on 40-hour schedules, Smith notes that there have been some changes in work patterns, with a still small but growing group of workers on "compressed" full-time weeks of less than 5 days. Surprisingly, she also finds some growth in the proportion of workers on part-time schedules who seem to "stretch" their work out over 6 or 7 days.

Susan Shank examines the data on workweek preferences and finds only moderate support for the hypothesis underlying the "backward bending labor supply curve," according to which an increase in rates of pay past a certain point induces workers to reduce their hours of work. Although the proportion of workers choosing fewer hours of work does grow as earnings rise, the category remains very small. Even among workers earning $750 or more per week, only about 10 percent of the men and 20 percent of the women were willing to trade hours of work—and the income linked to them—for additional leisure.

Earl Mellor focuses on the workday and finds that about 1 of 8 full-time workers were on flexitime or other schedules that allowed them to vary the start and end of their daily work. The great majority were on typical daylight schedules, with about one-fifth reporting 8:00 a.m. to 5:00 p.m. as their schedules. About 6 percent worked predominantly in the evening, 3 percent on the "night shift," and 4 percent on rotating shifts.

The data on multiple jobholders are examined by John Stinson. He finds a particularly sharp increase in the number of women with two jobs, which is another sign of the growing strength of their ties to the job market. Nearly 5 percent of working women are now multiple jobholders.

The new data on home-based work are analyzed by Francis Horvath, who observes that most of the persons reporting such work are full-time workers who, apparently, do only a small part of their work at home. Only one-tenth of these workers were engaged in manufacturing activities, an area of traditional concern in the field of labor legislation. Most prevalent were those employed in offices, sales, and miscellaneous services.

Bruce Klein uses the May 1985 data to construct measures of absences. He finds that the proportion of workers with an absence in the reference week for the survey was only 4.7 percent, a rate considerably lower than rates which had been computed for several years until 1980. He hypothesizes that this decline in absences, confirmed by other data, may reflect several factors such as: the job reduction in some industries, which is likely to have fallen most heavily on workers with high rates of absenteeism; the likely impact of such cuts on other workers, who might have reduced their rates of absenteeism so as not to jeopardize their jobs; and the positive measures adopted by some employers to reward the workers with few absences.

What if you are your own employer?

In analyzing the May 1985 data on work schedules and related topics, we decided to make a small departure from the typology generally used in the display and analysis of data from the Current Population Survey. Specifically, we decided to focus mainly on wage and salary workers and, in doing so, to exclude from this universe those who are the nominal employees of corporations which they own. While "wage and salary workers" in a technical sense—and treated as such in the usual display of employment data from the CPS—these persons (numbering 2.8 million in May 1985) exhibit many of the traits and work patterns of the typical self-employed workers. For this reason, in most of the analyses which follow, these "incorporated self employed" are broken out of the total wage and salary universe and either shown separately or merged with the other self-employed. The smaller group of "unpaid family workers" (those 500,000 who, although unpaid, worked at least 15 hours a week in a family owned enterprise) are also either shown separately or merged with the self-employed workers (those not incorporated), with the combined group, totaling 9.8 million, generally shown as "all other workers." This allows the analyst to focus more clearly on the wage and salary workers who are truly working for someone else.

Wayne Howe examines the data on the characteristics of the workers employed by temporary help agencies. This has been a rapidly growing sector of employment in recent years. Howe finds that, relative to other workers, those who are employed by temporary help agencies are more likely to be younger and to work part time. Their group contains relatively large proportions of women and blacks, who are heavily concentrated in clerical work and in what might be called "industrial help" occupations.

Darrell Carr looks at the new data on workers receiving overtime pay. These cover not only the persons working more than 40 hours a week; they extend also to those receiving overtime premiums for some hours, even though the weekly total does not exceed 40. He notes that out of 10.5 million workers with some overtime pay for work performed during the reference week for the May 1985 survey, about 1.6 million had actually worked 40 hours or less.

Taken together, these articles improve our understanding of the work practices of American men and women. Of course, further analysis of the data on which the findings are based is still possible. Moreover, other issues could be addressed using these data. For example, where there are multiple workers in a family one might want to determine how the schedules of one member correspond to those of other members. The effect of the presence of children on the work schedules and workweek preferences of the parents might also be explored further. And a construction of a bridge between the data on work schedules and preferences of workers and those on family income might also be undertaken. These are complex and time-consuming undertakings, but with potentially large payoffs in the form of further insights into the day-to-day work lives of American men and women. ☐

FOOTNOTES

[1] The work experience data are published annually. For the most recent data, see Shirley J. Smith, "Work experience profile, 1984: the effects of recovery continue," *Monthly Labor Review*, February 1986, pp. 37–42.

[2] The data on when the persons outside the labor force have last worked are not currently published and may be subject to significant bias, particularly because of a phenomenon known as "telescoping." This relates to a possible tendency among survey respondents to report certain events as having occurred in the recent past, when, in fact, they had occurred earlier. To the extent that some of the persons who have been outside the labor force more than 1 year report that they left their last job in the most recent year, there would be an overestimation of the number exiting the labor force and, by inference, of those entering it over the year in question.

[3] While very revealing, the gross flow data are subject to serious statistical problems and may also overestimate the flows into and out of the labor force. See Paul O. Flaim and Carma R. Hogue, "Measuring labor force flows: a special conference examines the problems," *Monthly Labor Review*, July 1985, pp. 7–17.

[4] See Ellen Sehgal, "Occupational mobility and job tenure in 1983," *Monthly Labor Review*, October 1984, pp. 18–24.

[5] Robert E. Hall, "The Importance of Life Jobs in the U.S. Economy," *American Economic Review*, September 1982.

[6] Shirley J. Smith, "Revised worklife tables reflect 1979–80 experience," *Monthly Labor Review*, August 1985, pp. 23–30.

The growing diversity of work schedules

While the 40-hour, 5-day workweek remains the schedule of choice for most employers and workers, a recent study shows evidence of the emergence of new forms of extended and compressed work schemes

SHIRLEY J. SMITH

During any given week, the composition of the active segment of the work force undergoes many changes. Each industry and occupation has its own cycle of activity and draws on a somewhat different labor pool. Most production occurs Monday through Friday (or Saturday), frequently with the aid of evening and night shifts on those days. However, some economic activities, such as continuous manufacturing processes, agriculture, transportation and communications, health and certain other services, and retail sales, extend beyond the Monday to Friday schedule. In fact, these activities predominate on Saturday and Sunday. Each demographic group establishes itself within this variable labor market according to the types of jobs its members can obtain and the work schedules they are able to accommodate in their personal lives.

This article, based on the May 1985 Current Population Survey (CPS) supplement, examines several of the work schemes adopted by U.S. workers on their principal jobs. The schedules discussed include the "standard workweek" (that is, 40 hours in 5 days); compressed and extended schedules; part-time, full-time, and long hours schemes; and variations in the number of days worked per week, and in the choice of specific days worked. Where possible, patterns observed in May 1985 are compared with those observed previously to judge the nature and pace of change. The CPS surveys of May 1973 and May 1979 are used in this comparison to minimize distortions due to business cycle fluctuations.

The 'standard workweek'

It has been estimated that at the turn of the century the average worker spent about 53 hours per week on the job.[1] The passage of the Fair Labor Standards Act of 1938 (FLSA) established a standard workweek of 40 hours' duration for nonsupervisory employees of firms engaged in interstate commerce.[2] Over the ensuing years, concern about workers' health led to many Federal and State statutes and union contracts which stipulated a second standard: the 8-hour day. Under these provisions, many persons were guaranteed overtime pay for hours worked in excess of this daily standard. The logical outgrowth of these regulations was a third implicit standard, the 5-day workweek.

Persons who were teenagers when the Fair Labor Standards Act was passed had reached retirement age by 1985. In their lifetimes, the coverage of the act has been extended to nearly 60 percent of all wage and salary workers,[3] and has become not only a matter of law, but a social norm. More than half of all nonfarm wage and salary workers and roughly two-thirds of those working full time report that they work exactly 40 hours per week, proportions which have changed little since the CPS began monitoring usual hours worked on principal jobs in 1973. (See table 1.)

Shirley J. Smith is a demographic statistician in the Division of Data Development and Users' Services, Office of Employment and Unemployment Analysis, Bureau of Labor Statistics.

Because the 40-hour week is so popular, both with employers and employees, most work schedule data are so strongly unimodal that it is difficult to recognize the changes which occur. Measures of central tendency such as means and medians are totally dominated by the standard schedule, and thus reveal little variation over time. Yet closer examination of the data will show that the work schedules of American workers have been changing, and are becoming increasingly diverse.

Catalysts in this redistribution include the stagnation of employment in manufacturing industries and the rapid growth of certain services and retail trade. Despite a 27-percent expansion in all wage and salary employment since May 1973, employment in manufacturing in May 1985—20.4 million—was no larger than it had been 12 years before. Not only was the number of manufacturing jobs more or less frozen, but the work schedules of those holding jobs had even contracted.

Some of this change is apparent in employers' reports of scheduled hours. The Bureau of Labor Statistics' Area Wage Surveys indicate that the average workweek for full-time day-shift plant workers decreased by 0.8 hours between 1973 and 1985. Over the same period, the schedule of full-time office workers in the private sector rose by 0.2 hours, with the result that the workweek of these two large groups converged markedly.[4] Whereas the average plant worker's 1973 workweek was scheduled to last 1.5 hours longer than that of his or her counterpart in the office, by 1985 the differential had narrowed to 0.5 hours.[5]

Despite the evident restructuring of plant schedules, CPS estimates of mean and median usual weekly hours for workers in all industries (38.4 and 40.4 respectively in 1985) have hardly changed since 1973. Similarly, the median length of a full-time workweek has remained nearly fixed at 40.6 hours. For full-time workers, the mean rose slightly from 42.4 to 42.6 between 1973 and 1985, suggesting a slight increase in the number of hours routinely worked. In fact, this increase was due to a decline in the number of full-time workers reporting 35- through 39-hour schedules, rather than a rise in the numbers working 41 hours or more.

Table 1. Prevalence of 40-hour, 5-day, and 40-hour/5-day workweeks among nonagricultural wage and salary workers, 1973, 1979, and 1985

Work schedule and year	Proportion of—					
	All nonagricultural workers			Full-time nonagricultural workers		
	Total	Men	Women	Total	Men	Women
40-hour week						
1973	55.3	(1)	(1)	66.1	(1)	(1)
1979	56.0	59.1	51.8	67.6	65.1	72.0
1985	53.7	56.8	50.1	66.2	63.6	70.1
5-day week						
1973	74.1	(1)	(1)	81.4	(1)	(1)
1979	75.4	75.4	75.4	83.5	79.4	90.4
1985	73.5	73.6	73.3	82.6	78.8	88.4
40-hour/5-day week						
1973	52.9	(1)	(1)	63.3	(1)	(1)
1979	53.3	56.1	49.6	64.4	61.7	69.0
1985	50.4	53.0	47.4	62.2	59.3	66.4

[1] Estimate not available.

NOTE: Estimates reflect data for wage and salary workers and the incorporated self-employed age 16 and over. Figures for May 1973 exclude private household workers.

The median is cited to underscore the tremendous stability of these estimates. Whatever changes have occurred in the tails of the distribution, well over half of employed Americans work the standard schedule, and the remainder continue to be evenly spaced above and below that figure. It requires a fairly visible restructuring of the hours distribution to relocate the median. For this reason, the increase in median hours per week reported by part-time workers (from 20.2 in 1973 to 23.0 in 1985) is noteworthy.

Evidence of the increased diversity of work schedules can be seen in the following distributions for nonfarm wage and salary workers (including the incorporated self-employed):

	1973	*1985*	*Change, 1973–85*
Median usual hours	40.5	40.4	−.1
Mean usual hours	38.6	38.4	−.2
Total nonfarm wage and salary workers (in thousands)[6]	69,971	94,879	24,908
Percent	100.0	100.0	–
1–24 hours	11.7	12.3	.6
25–29 hours	1.8	2.3	.5
30–34 hours	2.9	4.1	1.2
35–39 hours	7.5	7.4	−.1
40 hours	55.2	53.8	−1.4
41–48 hours	10.2	8.3	−1.9
49 or more hours	10.7	11.7	1.0

During intervening recessionary periods (1974–75 and 1980), May supplements showed the hours distribution to be shifted temporarily downward. A drop in overtime opportunities led to a temporary resurgence of the 40-hour scheme. However, a comparison of schedules during these periods of relative prosperity reveals that both part-time and the very extended hours schedules have gained proportionately to the more conventional schemes.[7]

It is no surprise that two separate trends were in evidence among those working long hours. The class working 41 to 48 hours, which is dominated by precision production, craft, and repair workers and operators, fabricators, and laborers—the "blue-collar" occupations most affected by the decline in manufacturing—registered relative contraction over the study period. Meanwhile, the group working 49 hours or more, in which "white-collar" occupations such as managers and persons in professional, technical, sales, and administrative support positions outnumber the "blue-collar" group, registered a slight gain.

Usual days per week

The 5-day workweek is even more prevalent than is the 40-hour week. In 1985, nearly three-quarters of the work force, and more than four-fifths of those employed full time reported schedules of 5 working days. (See table 1.) Both mean (4.9) and median (5.5) usual days per week have remained nearly constant since 1973.

Even so, the distribution of total workers by usual days of work corroborates the impression that schedules have become more diverse:

	1973	*1985*	*Change, 1973–85*
Total nonfarm wage and salary workers (in thousands)[6] . .	69,971	94,879	24,908
Percent	100.0	100.0	—
1–3 days	6.5	7.8	1.3
4 or fewer days	9.8	13.0	3.2
4.5 or fewer days	10.3	13.9	3.6
5 days	74.1	73.6	–.5
5.5 or more days	15.5	12.5	3.0
6 or more days	11.5	9.7	–1.8
7 days	1.7	2.2	.5

Observations made during recessions show the 5-day week to be particularly prevalent in unstable times. Yet, over the 12 years shown, both compressed and very extended workweeks made gains at the expense of the 5- to 6-day week.

Table 2. Standardized percent change in the incidence of various weekly work schedules, May 1973 to May 1985

Usual hours worked per week	Usual days worked per week: Total	1-3 days	4-4.5 days	5 days	More than 5 days

49 or more hours	13	(2)	282	48	–14

[1] The number of nonagricultural wage and salary workers reporting work schedules rose by 35.6 percent between May 1973 and May 1985. This figure has been subtracted from the observed growth rate for each cell so that negligible values signify growth in pace with the total, negative values a lag, and positive values relative expansion.

[2] Cell frequency is too small to warrant this computation.

NOTE: Estimates are for wage and salary workers and the incorporated self-employed age 16 and over. Figures for May 1973 exclude private household workers.

Emergence of alternate schedules

The heavy clustering of reported schedules in standard patterns obscures our view of the unconventional schedules which have been gaining popularity in the workplace. One way to identify them is to determine which patterns have registered the highest rates of growth in recent years. Between May 1973 and May 1985, the number of nonfarm wage and salary workers for whom work schedules were tabulated rose by 36 percent. We have estimated the corresponding growth rates within various work schedule groupings, and from each subtracted this average rate of growth. The resulting figures (table 2) illustrate which schemes have gained in popularity (positive values) and which have lost (negative entries).

Several interesting patterns emerge from this computation. The growth of employment in the more conventional schemes has indeed been more sluggish than that in other schedules. For instance, the number of persons on a 40-hour/5-day week has lagged overall growth by 6 percentage points. Two other 5-day schemes (1- through 29-hour and 35- through 39-hour workweeks) have lagged even further behind.

Both the extended days and extended hours schemes registered net declines during this period, almost entirely due to the drop in the 41- through 48-hour/extended-week scheme. Between May 1973 and May 1985, the absolute number of workers registering this schedule dropped by more than a third.

Although this was a profound setback to the extended workweek (5½ days or more), lengthy workweeks appear to have gained some momentum among persons working 40 hours or less. The growing dispersion of work hours for these individuals probably reflects the expansion of weekend employment in retail sales and services, both of which draw from pools of supplemental part-time help.

Among alternate schedules, the most familiar form is generally the "compressed workweek," normally defined as 40 hours' work completed in 4 to 4½ days. Employment in such schemes grew about 4.5 times as fast as did total employment during the 12 years preceding May 1985. But other forms of compression were also in evidence. For instance, those working long workweeks (41 hours or more) appeared increasingly likely to compress them into a span of 5 days—or even less—thereby reserving a block of time for other activities. There was even some evidence of a growth in "compressed part time," whereby persons working 30 to 34 hours did so in 3 days or less.

The small representation of most of these groups in the work force means that even rapid growth of these cells can have little impact on aggregate measures. It would probably take many years of accelerated growth for these schemes to become popular alternatives to those with which we are most familiar. Certain less dramatic changes (such as the rise in the 5-day/41-or-more-hour week—another "compressed long hours" scheme) are more easily spotted because they affect larger segments of today's work force.

When the interval is broken into phases before and after May 1979, similar computations show that three schedule groups have lagged throughout the full interval. In addition to the declining 41- through 48-hour extended week (5½ or more days) scheme, the two 5-day schemes mentioned earlier (light part time of 1 to 29 hours and light full time of 35 to 39 hours) have experienced contraction.

The incidence of the 40-hour/5-day workweek actually kept pace with overall employment growth until 1979. The fact that it has not done so since that time is somewhat surprising, given the occurrence of two serious recessions in the early 1980's. The temporary effects of each must have been to force many overtime workers into this standard full-time pattern.

Since 1979, only one form of lengthy workweek has registered comparative gains: employment lasting 49 hours or more per week. Most of the gains noted have involved workers compressing these long hours into 5 or fewer days.

The conventional "compressed workweek" (full-time work completed in under 5 days) has been growing at an accelerated rate. While overall employment growth between 1979 and 1985 was 16 percent, this scheme grew more than four times as rapidly. The incidence of "dispersed" schedules, whereby relatively few hours of work occupy 5½ or more days per week, seems to have evolved since 1979.

Differences by sex

Labor analysts often discuss the convergence between male and female work patterns. Table 3, based on changes between May 1979 and May 1985, shows how this convergence is taking place. Standardized rates for men and women are juxtaposed to highlight similarities and contrasts.

The decline of the extended (more than 5-day) week is largely a male phenomenon. With the exception of the 41- through 48-hour variant, which has contracted for both sexes, there has been a growing concentration of women in extended workweek schemes.

The net drop in 41- through 48-hour schedules also has occurred largely among men. Although women, too, have been affected by the contraction of the 41- through 48-hour/5-day scheme, they seem to have more than offset its effects by compressing 41- through 48-hour schedules into 5 working days. Indeed, women appear to be pressing into long hour schemes, while men—who traditionally dominated those schemes—increasingly find themselves working compact and compressed schedules. It is difficult to determine how much of this shift has been voluntary, and how much the result of the changes in labor demand.

Both sexes report a declining concentration within standard schedules, and an increased likelihood of working 40 hours within 4 to 4½ days. Women seem to be moving up from light (1- through 29-hour) to more intense (30- through 34-hour) part-time schedules, and from light (35- through 39-hour) to more intense (41 or more hours) full-time schemes. At the same time, men are increasingly represented within the lighter hours schedules. There has been surprising growth in the number of men reporting part-time and light full-time schedules. The movement away from standard and extended workweeks to a compressed (4- through 4½-day) schedule is heavily dominated by men. Even for persons working long hours, this change effectively lightens the workweek by holding a block of time free for other activities. Men also seem largely responsible for the emergence of the "compressed part-time" schedule, perhaps because of growth in the number of protective service jobs.

Mean hours per day

With more than half of all wage and salary workers and more than 60 percent of those working full time still reporting a 40-hour/5-day schedule, it is no surprise that the average workday is approximately 8 hours in length. However, as workers begin to compress their hours into fewer days, this variable should begin to show those effects. This change is most evident among part-time workers, where the length of the average workday has increased by a full hour (from 4.2 to 5.2 hours) since 1973.

In addition to compression, some of the change is attributable to distributional factors. The work force (including the part-time component) aged over the study period,

[1] Overall growth rate for the period May 1979 to May 1985 was 16.0 percent. This figure has been subtracted from the observed growth rate for each 1979–85 cell of the table to derive the standardized values shown. Thus, for example, the growth of schemes involving 40 hours of work in 4 to 4.5 days was about five times that of all nonagricultural wage and salary employment.

[2] Overall growth of male nonfarm payroll employment from May 1979 to May 1985 was 10.3 percent. This figure has been subtracted from the growth rate of male employment in each work schedule to derive the standardized values shown.

[3] Overall growth of female nonfarm payroll employment from May 1979 to May 1985 was 23.5 percent. This figure has been subtracted from the growth rate of female employment in each work schedule to derive the standardized values shown.

[4] Cell frequency is too small to justify computation.

with its members becoming more committed to labor force involvement. The strengthening of the labor force attachment of women also contributed to this upward movement.

Variations by class of worker

The category of workers we have been discussing to this point, denoted "wage and salary workers," includes those who are nominal employees of corporations which they own. While this classification is consistent with other data series published by the Bureau, it hinders the analysis of the work practices of persons who truly work for someone else as distinguished from those who work for themselves, even if their firms are incorporated and they are on the payroll. Whether or not the business is incorporated, its owner faces a different set of risks and responsibilities than does the typical wage and salary worker. Work schedules reflect this difference. For instance, although wage and salary workers average just 38 hours of work per week, the unincorporated self-employed report an average of about 43 hours, and the incorporated, more than 48. Wage and salary workers claim to work an average of 4.8 days per week, as compared with 5.2 for each of the self-employed groups (which are treated jointly below). Unpaid family workers helping in family businesses often maintain even more erratic schedules tied to periods of peak need. Table 4 illustrates differences between the average work schedules of these groups of workers by sex.

In the past, work schedule reports have devoted little attention to the self-employed and their unpaid family workers. It is relatively difficult for these individuals to summarize their "usual" work patterns by answering a few simple questions. Recognizing that the estimates for these groups may be less robust than for wage and salary workers, we still regard them as important enough to discuss. Each class of worker maintains its own "niche" in the total employment picture. The industries within which entrepreneurs find it easiest to become established (including agriculture, retail trade, and certain services) by their very nature demand long hours and extended workweeks. Certain types of businesses are largely or predominantly self-employed operations. Certain groups of workers (for example, white men) are particularly likely to open their own family businesses. Recognition of these patterns helps to explain why work schedules of these groups differ so dramatically from the norm.

It should be noted that men are twice as likely as women to report self-employment (with the associated longer hours and workweeks). White men are almost three times as likely as blacks to do so. Women are four times as likely as men to supply unpaid family services, but in the aggregate, women are also more likely to be employed for a wage or salary.

Men who are self-employed average more days and many more hours of work per week than do their counterparts who are wage and salary workers. For women, the difference is much less pronounced. Overall, the self-employed are four times as likely as wage and salary workers to average 6 or more days of work per week. The evidence suggests that—at least for men—they also work more hours per day.

Table 4. Incidence of selected work schedules, by class of worker and sex, May 1985

Work schedules and sex	Class of worker

[3] Not available.
[4] Data are available only for the self-employed and unpaid family workers combined.

Who works weekends?

The class-of-worker variable is particularly relevant to the discussion of specific days of work. The level and character of economic activity is quite different on weekends than during the week. It is even different on Sunday than on Saturday. During the week, about 20 percent of all workers hold primary jobs in manufacturing, and another 20 percent work in professional service jobs. On weekends, these industries account for about 10 percent and 14 percent of all primary jobs, respectively. Retail sales workers, who represent only about 17 percent of the weekday work force, account for more than 34 percent of the population active in their main job on weekends.

The self-employed (whether incorporated or not), and the unpaid working members of their families, often operate businesses which serve active weekend markets. They also bear a greater responsibility for the continued operation of their businesses than do individual wage and salary workers, and their risks associated with taking time off are necessarily greater. Consequently, whereas fewer than 1 in 10 wage and salary workers maintain an extended (6- or 7-day) workweek, this is the usual schedule reported by more than 1 of every 3 self-employed persons and nearly half of all unpaid family workers.

Table 5 is a "snapshot" of the characteristics of persons who usually report to their primary job on various days of the week. (The categories are not mutually exclusive: some who work Monday to Friday are also included in weekend distributions, and so forth.) As the largest segment of the work force, wage and salary workers dominate each of the groups detailed in the table. However, their share drops from 88 percent during the week to 77 percent on Saturday and to 58 percent among those who work continuously.

On Saturday, the number of persons working at their primary job contracts to 28.9 million, about a quarter (27 percent) of its weekday size. Because fewer than 1 percent of those who work do so exclusively on weekends, the composition of weekend employment tells us as much about who has taken a break as about who is reporting to work. On Saturday, the percentage of overall employment accounted for by prime-aged men holds steady. That of prime-aged women drops sharply, but the proportionate decline is offset by greater work effort among teens, young adults, and men age 65 and over. On Saturday, the representation of the self-employed and unpaid family workers is roughly twice what it is during the week. Of the wage and salary workers who report to work, a disproportionate share hold part-time jobs.

Table 5. Employed persons who usually work on specific days of the week, by selected characteristics, May 1985
[In percent]

Worker characteristic	Total	Persons who usually work— Monday to Friday	Saturday	Sunday	7 days per week

[1] Data are not additive, as persons working on any or all weekdays may also work on weekends.

[2] Excludes the incorporated self-employed.

[3] Includes both the incorporated and the unincorporated self-employed.

[4] Detail will not add to 100 percent because Hispanics are included in both the white and black populations and because data for the "other races" group are not presented.

The primary work force contracts still further on Sunday, to 13.2 million—about an eighth of its weekday size. This is the day when prime-aged men are most likely to be taking a break from their main job. (We have no way of judging what share devote the day to secondary employment.) The group normally reporting to their main job on Sunday includes still larger shares of teens and young adults, more older men, and proportionately more prime-aged women. Although there is a slight drop in the activity of the self-employed (largely men), unpaid family workers (largely women, teens, and young adults) continue to be relatively active.

Of those who normally work at the same job 7 days per week, more than half are prime-aged men; 3 of 10 are women; and 4 of 10 are self-employed. Sixteen percent maintain extended part-time ("dispersed") schedules, mostly as wage and salary employees. The representation of blacks and Hispanics, which drops on weekends, is particularly low among those working 7-day weeks. Undoubtedly, one reason is the lower probability that they own or operate family businesses.

Work schedules by industry and occupation

We have already noted that the industrial composition of the work force varies during the week, and that the timing of labor demands within each industry affects the labor pool upon which it may draw. Table 6 summarizes, for major industries and occupational groupings, several of the work schedule features previously mentioned. Each category reflects a differing level of labor demand, both with regard to total hours and to scheduling within the week. For illustrative purposes, the groups have been ranked according to the mean number of hours their employees report working each week.

The association between hours requirements, days of work, and female participation in the industry or occupation is fairly strong. The more time the activity involves, the less attraction it seems to hold for women. Although the relationship to weekend work is less pronounced, a similar pattern is evident there as well.

Multiple jobholding

A separate discussion of multiple jobholding appears elsewhere in this issue, but it is worth taking a brief look at the effect of this practice on aggregate estimates of time spent at work.

The information in this article relates to the worker's primary job. For the small group of workers (5.4 percent) who held two or more jobs in the May 1985 reference week, the total hours and days reported will understate the actual amount of time spent at work. Because dual jobholding can be a functional equivalent to working long hours on a single job, there are many applications in which we might like to see the data tabulated for all jobs combined. A reestimation on this basis increases the share of the work force shown to be working more than 40 hours, and reduces the share working 40 hours or less. Overall, it expands the share working more than 40 hours by 12.3 percent, with still greater impact on the estimates for women (19.7 percent), blacks (17.0 percent), and men and women ages 16 to 24 (14.7 percent and 28.5 percent respectively).[8]

DESPITE THE FACT that the majority of workers still report maintaining a 40-hour/5-day workweek, there is evidence that this scheme has been declining in popularity. Employment in such schedules has lagged behind total employment growth since 1979. Throughout the 1973–85 period, long-hour/long-day schemes have been contracting, both for men and for women.

In their place, three other schemes are emerging. Both sexes have demonstrated increased readiness to work a simple compressed workweek, wherein 40 hours of work are completed in under 5 days. Those working more than 40 hours per week appear to be working more compact schedules within the confines of a 5-day week (or less), holding two or more days free for other activities. Among those working 40 hours or less, some appear to be adopting "work spreading" schemes, which distribute their hours over $5\frac{1}{2}$ or more days per week. The result is a diversification of schedules which has occurred without much corresponding change in the mean or median estimates of usual hours or days worked per week.

In the aggregate, men continue to work more hours per week, more hours per day, and more days per week than do women, and they are also more likely to work on weekends. Elements of the standard workweek thus continue to dominate overall work schedule distributions. Nonetheless, the growth of the female work force has been most rapid in long hours schedules and those involving $5\frac{1}{2}$ or more days per week, while the expansion of the male labor force has occurred primarily in shorter, more compact schedule groupings. □

FOOTNOTES

[1] For a discussion of past trends, see Janice Neipert Hedges and Daniel E. Taylor, "Recent trends in worktime: hours edge downward," *Monthly Labor Review*, March 1980, p. 4.

[2] The Fair Labor Standards Act became effective in 1940.

[3] See Employment Standards Administration, *Minimum Wage and Maximum Hours: Standards Under the Fair Labor Standards Act—1984 Report* (U.S. Department of Labor, 1984).

[4] These data exclude workers in contract construction; all governmental establishments and government-owned and operated businesses (such as water utilities, transit authorities, and so forth); medical and educational services; and administrative, executive, professional, and part-time employees. Also excluded are persons who are self-employed, or who work anything other than the day shift. See *Area Wage Surveys: Metropolitan Areas, United States and Regional Summaries, 1973–1974* and *1985* (Bureau of Labor Statistics).

[5] The May 1985 supplement to the Current Population Survey (CPS) requested information on usual rather than scheduled hours. As such, it picks up the added effects of routine overtime and uncompensated long hours. In addition, the CPS information has been collected from household respondents, rather than employers' records as in the Area Wage Survey. Results of the two surveys are not directly comparable, but should normally reinforce one another's findings.

[6] Figures for 1973 exclude private household workers, and those not reporting work schedules. Figures for 1985 have been adjusted to distribute nonresponse.

[7] If private household workers had been included in distributions for both years, it is likely that the drop of the 40-hour week and the rise of the 49-or-more-hour week would both have been somewhat less pronounced.

[8] There may still be some omissions, because no hours details were collected for tertiary jobs.

Shift work and flexitime: how prevalent are they?

New data reveal that shift work and flexitime are not widespread; only 1 of 10 full-time wage and salary workers is on an evening or night shift, and only 1 of 8 has a flexible schedule

EARL F. MELLOR

Although the needs of society require a diversity of work schedules, most Americans have traditional morning to late-afternoon hours. The great majority of full-time wage and salary earners begin work between 7 and 9 in the morning. The proportion who work in the evening or at night, or who are on flexible schedules, is rather small. In contrast, almost half of all part-time employees work schedules other than regular day shifts, and nearly one-fifth have some type of flexible scheduling. The incidence of shift work and flexitime varies by sex, race, age, and other characteristics, but differences are more apparent by occupation and industry.

These patterns are revealed in newly available data from the Current Population Survey (CPS), which asked questions on beginning and ending hours of work, shift work, and the availability of flexitime, to name a few. The information relates to people who were at work during the week of May 12–18, 1985, and was collected in a special supplement to the May 1985 CPS.[1]

Workday, from start to finish

Nearly 8 of 10 full-time wage and salary workers began their workdays between 7 and 9 a.m. during the survey reference week, with 8 a.m., by far, the most reported time. (See table 1.) With so many workers starting at these hours, it is not surprising that the most frequent quitting times were between 4 and 6 p.m., with 5 p.m. leading. Thus, traditional daytime shifts predominate, with 8-to-5, 7-to-4, 8-to-4, and 9-to-5 schedules being the most popular. Of the top 10 work schedules (of a possible 576) only one—the tenth ranked 3-to-11 p.m. shift—included a substantial number of hours outside the normal daylight span. (The times actually reported are rounded to the nearest hour when they are entered on the CPS questionnaire. For example, 8 a.m. refers to any reported time between 7:30 and 8:29. See appendix for further details.)

For part-time workers, 7 to 9 a.m. were the most frequently reported starting times, accounting for 45 percent of the total. The most popular quitting times were in the 3-to-5 p.m. span. As was the case for full-time workers, part-timers most often reported an 8 a.m. to 5 p.m. work day—but these hours accounted for only 4 percent of the part-time schedules. Part-time jobs—in terms of starting time, quitting time, and the overall schedule—were far less concentrated within the top 10 rankings. Whereas the top 10 schedules were reported by 71 percent of all full-time workers, they fit the pattern for only 29 percent of part-time workers.

Shift work

There are two ways to determine a worker's shift. One is based on the time the person begins and ends the workday;[2] the other is based on responses to a question regarding which shift persons considered themselves to usually work. The former method permits a precise definition (for example, a day shift is one in which half or more hours worked are between 8:00 a.m. and 4:00 p.m.), and thus a shift work definition can be tailored to the user's particular needs.

Earl F. Mellor is an economist in the Division of Employment and Unemployment Analysis, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

Table 1. Most prevalent beginning and ending hours of work and overall schedules of wage and salary workers, by usual full- and part-time status, May 1985

[Numbers in thousands]

Rank	Beginning time			Ending time			Overall daily schedule		
	Time	Number of workers	Percent of all workers	Time	Number of workers	Percent of all workers	Schedule	Number of workers	Percent of all workers
Full-time workers									
1	8 a.m.	29,116	39.7	5 p.m.	25,807	35.2	8 a.m. to 5 p.m.	16,025	21.8
2	7 a.m.	17,532	23.9	4 p.m.	16,750	22.8	7 a.m. to 4 p.m.	7,947	10.8
3	9 a.m.	11,004	15.0	6 p.m.	8,440	11.5	8 a.m. to 4 p.m.	7,256	9.9
4	6 a.m.	3,864	5.3	3 p.m.	6,645	9.1	9 a.m. to 5 p.m.	6,172	8.4
5	3 p.m.	2,043	2.8	7 p.m.	2,896	3.9	7 a.m. to 3 p.m.	4,087	5.6
6	10 a.m.	1,597	2.2	12 midnight	1,927	2.6	8 a.m. to 6 p.m.	2,902	4.0
7	4 p.m.	1,526	2.1	11 p.m.	1,816	2.5	9 a.m. to 6 p.m.	2,726	3.7
8	11 p.m.	1,110	1.5	8 p.m.	1,355	1.8	7 a.m. to 5 p.m.	2,585	3.5
9	5 a.m.	814	1.1	2 p.m.	1,256	1.7	7 a.m. to 6 p.m.	1,477	2.0
10	12 midnight	634	.9	7 a.m.	1,142	1.6	3 p.m. to 11 p.m.	1,238	1.7
Part-time workers									
1	9 a.m.	3,179	18.2	5 p.m.	2,481	14.2	8 a.m. to 5 p.m.	703	4.0
2	8 a.m.	3,111	17.8	4 p.m.	2,192	12.5	9 a.m. to 5 p.m.	651	3.7
3	7 a.m.	1,605	9.2	3 p.m.	1,962	11.2	9 a.m. to 3 p.m.	602	3.4
4	10 a.m.	1,517	8.7	2 p.m.	1,490	8.5	8 a.m. to 4 p.m.	550	3.1
5	4 p.m.	1,328	7.6	6 a.m.	1,311	7.5	7 a.m. to 4 p.m.	494	2.8
6	5 p.m.	1,318	7.5	9 p.m.	1,238	7.1	5 p.m. to 9 p.m.	449	2.6
7	3 p.m.	993	5.7	10 p.m.	1,106	6.3	9 a.m. to 4 p.m.	421	2.4
8	11 a.m.	782	4.5	1 p.m.	979	5.6	8 a.m. to 3 p.m.	409	2.3
9	12 noon	637	3.6	12 noon	967	5.5	8 a.m. to 12 noon	405	2.3
10	1 p.m.	605	3.5	8 p.m.	767	4.4	8 a.m. to 2 p.m.[1]	398	2.3

[1] There were also 398,000 workers on a 9 a.m. to 2 p.m. schedule.

NOTE: Data refer to wage and salary workers, excluding the incorporated self-employed, who were at work during the reference week. Times refer to beginning and ending hours most days of the week and are rounded to the nearest whole hour.

However, this makes no allowance for split or rotating shifts. The latter method allows the respondents to say what they consider is the shift usually worked. This concept permits the incorporation of split and rotating shifts as well as reduces the reporting of deviations from the usual work schedule which may have occurred in a given week. It is the self-identified notion of shift which is the focus of the analysis in this article.[3]

Generally speaking, shift work is a great advantage to employers who need to match production with demand, accommodate the nature of certain production processes, and reduce the cost of capital per employee. However, except for those who cannot work at a regular daytime job (for instance, students) and those who prefer evening or night hours, shift work often does not benefit workers or their families. In fact, the effects of shift work—particularly night and rotating shifts—can be quite disruptive, with such consequences as sleeping, digestive, and nervous disorders and interference with family relationships.[4]

Of the 73.4 million full-time wage and salary workers who were at work during the survey reference week, 61.7 million, or 84 percent, described their usual work period as a "regular daytime schedule." Of the remaining 11.6 million —called "shift workers"[5]—most worked an evening shift (4.6 million), followed by rotating (3.1 million), night (2.0 million), and split shifts (about 540,000). A substantial number (1.4 million) worked some other schedule; presumably, this would include daytime workers who felt their schedules were not "regular," and may include some on flexitime who vary their beginning and ending times.

Men were more likely than women to be shift workers. This was the case also in each age group, except for teenagers. (See table 2.) More than one-quarter of the teens who worked full time were not on a regular daytime schedule. Among adult men, the incidence of shift work decreased with age, reaching 15 percent for the 45 and over age groups. For adult women, the incidence fell with age to 11 percent for 35- to 44-year-olds, and then rose slightly in the upper ages, reaching 13 percent for those 65 and older. The evening shift accounted for one-third to one-half of all shift workers, except men age 65 and over.

Blacks were more likely than whites or Hispanics to be shift workers. Hispanic men were as likely as white men, but considerably less likely than black men, to work other than a regular daytime schedule. Hispanic women, however, were less likely than both white and black women to be shift workers. Married (spouse present) persons had much smaller proportions working shifts than either singles or those of other marital status. Given that single workers are usually younger than married workers, the higher incidence is probably the result of age differences. Younger workers have less seniority on the job—hence, less choice in shift selection. In addition, youths tend to be in the types of jobs that are more likely to require shift work. Another consideration is that married workers may be less willing to work other than day schedules.

Among occupational and industry groups, shift work is associated with skill and product demands which cannot be satisfied by daytime schedules alone. These include businesses whose customers wish to shop until 9 or 10 at night, or even around the clock; the need for police and fire protection and health care 24 hours a day; and the overnight delivery of goods. On the supply side, some production processes requires continuous operation, as it would be too costly to shut down each evening and restart each morning. In other cases, high capital costs necessitate around-the-clock utilization.

The incidence of shift work was 10 percent or less among full-time workers in managerial and professional jobs; administrative support, including clerical jobs; and farming, forestry, and fishing occupations. However, within some of these occupations, there were groups with an incidence of shift work of 20 percent or higher—for example, health diagnosing, assessment, and treating occupations among professional workers, and mail and message distributing workers within the administrative support category. (See table 3.) Protective service workers (61 percent) were most likely to work shifts (in fact, 22 percent worked rotating shifts), followed by workers in food (43 percent) and health services (36 percent). Other occupational groups traditionally associated with shift work—the operators, fabricators, and laborers group, and salesworkers in retail trade and personal services—had about one-quarter on shift work.

For most occupations, the evening shift was the most frequent departure from a regular day schedule. The exceptions were health professionals, retail and personal salesworkers, protective service workers, and motor vehicle operators, who reported rotating shifts more frequently than evening shifts. Night shifts were the least common, accounting for about 3 percent of all full-time workers. But, the incidence of night shifts was well above average for some in the groups noted for the likelihood of rotating shifts.

Shift work was more prevalent in the private sector (16.5 percent) than the public sector (12.8 percent). Among goods-producing industries in the private sector, shift work was highest in mining and lowest in construction. (See table 3.) In manufacturing, it was most frequent in areas requiring continuous production (because startup and shutdown costs are high), such as primary metals, automobiles, paper products, chemicals, and rubber and plastics. In the service-producing sector, shift work was most often reported in transportation, retail trade (particularly in eating and drinking places), personal services, entertainment and recreation, and hospitals—all activities for which product demand goes

Table 2. Shift usually worked by full-time wage and salary workers, by selected characteristics, May 1985

[Percent distribution]

Characteristic	Total employed (in thousands)	Regular daytime schedule	Shift workers					
			Total	Evening shift	Night shift	Rotating shift	Split shift	Other shift

NOTE: Data refer to wage and salary workers, excluding the incorporated self-employed, who were at work during the reference week. Dash indicates fewer than 0.05 percent.

beyond traditional daytime hours.

The incidence of shifts was much higher for those who did not usually work 5 days a week. Almost two-thirds of those working full-time on a 3-day-a-week schedule and just over a third of those on 4-day schedules considered themselves shift workers. Half of the 3-day workers reported working "other shifts." This should be expected, because each day's work would average at least 12 hours and would not be considered by many as a regular daytime shift, even if most of the hours fell during daytime hours. About 29 percent of those working a 6-day week and 38 percent of 7-day workers considered themselves shift workers.

Of those who reported a reason for not working a regular daytime schedule, 28 percent cited voluntary reasons, including better arrangements for child care or care of other family members, better pay, or time for school. Of the 72 percent giving "involuntary" reasons, 9 of 10 cited the schedule as a requirement of the job; most of the remainder reported they worked shifts because they could not find any other job.

Part-timers were about three times as likely as full-time workers to work other than a regular daytime schedule. Employers often hire part-time help to cover periods of peak demand, which may be as short as 3 or 4 hours on weekdays and may require nonconventional working hours. This is the case, particularly in retail sales and in entertainment and recreation. Many seeking part-time work, especially students, are able to work only evenings or weekends. Nearly half of all part-time workers and four-fifths of the 16- to 19-year-olds were shift workers. About one-quarter of the part-timers worked in the evening. (See table 4.) Employees in sales, service (particularly protective service), transportation and material moving, and in handler, equipment cleaner, helper, and laborer jobs were most likely to work other than a regular daytime schedule. Seven of ten part-time workers in protective service jobs were on shifts.

Flexible schedules

Under flexitime, employees can vary the times their workdays begin and end. The arrangements vary among establishments, and even among units within an establishment, depending on such factors as production, customer, and other coverage requirements; public laws and collective bargaining agreements; and the attitudes of individual managers and supervisors.

The amount of flexibility made possible by flexitime arrangements varies—ranging from as little as 30 minutes to 3 hours or more. Some plans permit variation in the number of hours worked per day, and in some cases, even the total number of hours worked each week, or pay period, and provide for the accumulation of "credit hours." Nearly all plans have a "core-time" requirement: all employees must work during the core time every day, or in some cases, on specified days of the week. A flexitime plan may be a formal document with detailed definitions, rules, and procedures, or it may be so informal that it is not explicitly identified as a flexible work schedule.[6]

Some potential advantages of a flexitime program are decreased tardiness, added hours of service to the public, smoothing rush-hour traffic peaks, larger blocks of employee leisure time, facilitating child care, and better

[1] Data not shown where base is less than 75,000.

NOTE: Data refer to wage and salary workers, excluding the incorporated self-employed, who were at work during the reference week.

scheduling of the work force to coincide with variations in the workload. Potential problem areas include the added need for managers and supervisors to schedule and plan the work flow and ensure the coverage of critical functions, the possible lack of supervision at some hours, added timekeeping needs, and nonlabor costs associated with more hours of operation (for example, heating and cooling).[7]

About 9.1 million full-time wage and salary workers (excluding the incorporated self-employed) who worked during the survey reference week in May 1985 were reported as having a work schedule which permitted them to vary their beginning and ending hours of work. (See table 5.) This was 12.3 percent of the covered workers. The incidence of flexible scheduling was lowest for teenagers (9.3 percent) and highest for the 35 to 44 and 65 and over age groups. Men were more likely than women to have flexibility in their work day, as were whites, compared with their black or Hispanic counterparts.

Among occupational groups, the ability to vary work hours ranged from 4 percent for machine operators, assemblers, and inspectors to 20 percent for those in sales occupations. For some more detailed classifications, the incidence was more than 30 percent, such as mathematical and computer scientists; natural scientists; technicians, except health, engineering, and science; and sales representatives (commodities except retail). The incidence was higher for men than for women for each occupational, age, and race or Hispanic category.

The likelihood of flexible scheduling was slightly higher in the private sector (12.6 percent) than in the public sector (11.3 percent). However, it was 20 percent in the Federal Government, where many agencies have formal flexitime programs. Within the private sector, those in service-producing industries (at 14.5 percent) had higher proportions with the freedom to vary work times than those in goods-producing industries (9.8 percent). Among industry groups, the incidence ranged from under 5 percent in furniture and fixtures, textiles, and apparel, to 15 percent or more in agriculture, printing and publishing, wholesale trade, finance, insurance, and real estate, business and repair services, personal services, entertainment and recreation, and the "other" professional services category, which includes legal services, membership organizations, and engineering, architectural, and surveying services.

Employees on regular daytime schedules were more likely to have the ability to vary their starting and ending hours (12.7 percent) than those on evening shifts (6.6 percent), night shifts (8.2 percent), or rotating shifts (10.8 percent). Nearly one-quarter of those on split shifts had either flexitime or some other scheduling arrangement permitting flexibility.

Part-time workers were more likely than their full-time counterparts to have flexibility in the scheduling of their work, with 3.3 million (18.6 percent) being able to do so. As with full-time workers, the proportion of men reporting flexibility was higher than that of women (19.8 versus 18.0 percent.) □

FOOTNOTES

[1] Statistics on wage and salary workers usually include self-employed workers whose businesses are incorporated because from a legal standpoint they are the paid employees of a corporation. However, they are excluded from the analysis here, as the primary interest in the scheduling of work lies in a universe of workers limited to those who work for someone else. To have a consistent universe throughout the article, data are limited to those who actually worked during the survey reference week, because some of the data were collected only for this group.

[2] Information on beginning and ending hours should not be used to indicate the number of hours worked per day—a statistic available through another question in the May 1985 survey. As previously mentioned, the times are rounded. For example, a 9:00 to 5:30 schedule would appear as 9:00 to 6:00. Because most workers usually arrive at work a few minutes before the required start time, someone who has a 7:30 to 4:00 work requirement, but actually arrives at 7:25 most days (and "punches in" accordingly), would be tallied as 7:00 to 4:00 if that earlier time was reported as the starting time. Both factors may combine to partially explain the large number of those with such 10-hour spans as 8-to-6 and 7-to-5 schedules. Accordingly, an 8-hour work requirement of 8:30 to 5:30 (less an hour for lunch) may appear as 8 to 6. In addition, proxy respondents may not know precise starting and ending times and may report the times an employee departs from and returns home. The span also includes any time not worked, such as lunch and other breaks and the time between the work periods of split shifts—which vary in length among workers.

Hedges and Edward Sekscenski, "Workers on late shifts in a changing economy," *Monthly Labor Review*, September 1979, pp. 14–22, for previously published data on shift work. Data published in this article are not comparable to those previously published on the subject.

[4] See Hedges and Sekscenski, "Workers on late shifts"; and Peter Finn, "The effects of shift work on the lives of employees," *Monthly Labor Review*, October 1981, pp. 31–35.

[5] Although a regular daytime schedule is, strictly speaking, a "shift," the term shift work is used here to describe only those schedules other than a "regular daytime schedule."

[6] Some of the variations of flexitime used among the plans covering Federal Government employees are flexitour, gliding time, variable day, variable week, and maxiflex. See *The Federal Employees Flexible and Compressed Work Schedules Act of 1978: An Overview of the Experimental Program for Federal Agencies* (Washington, U.S. Office of Personnel Management, 1979).

[7] See John D. Owen, *Working Hours* (Lexington, MA, Lexington Books, 1979), which has a thorough discussion of alternative work schedules, including the practicality of flexitime in different work situations. For testimony which cites both the merits and limitations of flexitime, see *Flexible and Compressed Work Schedules* and *Federal Employees Flexible and Compressed Work Schedules Act*, hearings before the Subcommittee on Human Resources of the Committee on Post Office and Civil Service, U.S. House of Representatives (Washington, Government Printing Office, 1982 and 1985, respectively).

APPENDIX: Notes on the data

Unless otherwise indicated, information in this article covers wage and salary workers, excluding the incorporated self-employed, who reported having worked during the week of May 12–18, 1985. Coverage includes both the private and public sectors and workers both in and out of agricultural industries. The data were collected for the Bureau of Labor Statistics by the Bureau of the Census as part of the May 1985 Current Population Survey (CPS). The CPS employs a scientifically selected sample of about 59,500 households in all 50 States and the District of Columbia.

Information on beginning and ending hours of work were obtained from responses to the following questions:

34. LAST WEEK at what time of day did . . . begin work on this job most days?
35. LAST WEEK at what time of day did . . . end work on this job most days?

Answers were coded in 1-hour increments, centered on the hour. For example, answers ranging between 4:30 and 5:29 p.m. were coded as 5:00 p.m.

Information for most of the data on shift work was obtained from the following:

36. Which of the following best describes the hours . . . usually works at this job?
    - A regular daytime schedule ...... ○
    - A regular evening shift .... ○
    - A regular night shift .... ○
    - A rotating shift—one that changes periodically from days to evenings or nights .... ○
    - A split shift—one consisting of two distinct periods each day .... ○
    - Other .... ○

The May 1985 data on shift work are not comparable to those which were published for the 1973–80 period. The earlier data were based on beginning and ending hours of work questions (as in 34 and 35 above). At that time, the day shift was defined as one at which the majority of hours worked was between 8 a.m. and 4 p.m.; the evening shift had a majority of its hours between 4 p.m. and midnight; and the night shift had a majority of its hours worked between midnight and 8 a.m. In the event of a tie (for example, 12 noon to 8 p.m.), day took precedence over evening, and evening took precedence over night. "Shifts" were limited to 6- to 12-hour periods; those shorter or longer were classified as "miscellaneous" shifts. In addition, the 1973–80 data excluded farm workers but included any self-employed workers whose businesses were incorporated. The 1985 data are based on the self-identification of usual shift; the data include farm workers and exclude self-employed workers.

A limited amount of the 1985 shift work data was cross-tabulated according to the old definition of shifts. Of those reporting a regular daytime schedule, 97 percent would have been classified as working a day shift based on beginning and ending hours. There is far less conformity among those tabulated as working evening (90 percent) or night (63 percent) shifts, as many of these would have fallen into the miscellaneous category based on the "old" way of tabulating shifts. As expected, those reporting that they usually work a rotating shift were distributed among each of the categories based on beginning and ending hours; and many of those reporting that they usually work a split or "other" shift would have fallen into the previous "miscellaneous" category.

The data on the presence of flexitime were obtained from the question:

40. Is . . . on flexitime or some other schedule that allows workers to vary the time they begin and end work?

Yes .... ○
No .... ○
Don't know ... ○

The May 1985 data on flexitime are not comparable to those collected in May 1980, because of a difference in coverage. The earlier survey included self-employed workers whose businesses were incorporated (most of whom—by definition—can vary their work hours) and excluded farm workers, while the 1985 survey did not ask the flexitime question to the incorporated self-employed, but did include farm workers. Even though the 1985 data indicated only a small rise in the incidence of flexible work times—from 11.9 percent to 12.3 percent for full-time workers—the rise would have been larger if the incorporated self-employed had been included.

A note on communications

The *Monthly Labor Review* welcomes communications that supplement, challenge, or expand on research published in its pages. To be considered for publication, communications should be factual and analytical, not polemical in tone. Communications should be addressed to the Editor-in-Chief, *Monthly Labor Review*, Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

Moonlighting by women jumped to record highs

An important, but small, proportion of Americans work at two jobs or more; they do so principally for financial reasons such as meeting regular expenses or paying off debts and also to explore new careers while still holding on to their primary jobs

John F. Stinson, Jr.

According to a survey conducted in May 1985, multiple jobholders totaled 5.7 million, 5.4 percent of all employed workers. This was up from 4.9 percent in 1980 and was the highest level in more than 20 years. Data from the same survey confirm the continuance of two long-term trends: an increasing number of women among the moonlighters and a decline in the proportion of multiple jobholders with at least one job in agriculture.

These findings are from a special survey of work patterns of American workers.[1] Multiple jobholders, as identified in this survey, are those employed persons who, during the survey reference week, either (1) had jobs as wage or salary workers with two employers or more; (2) were self-employed and also held a wage and salary job; or (3) were unpaid family workers on their primary jobs but also held wage and salary jobs.[2] The primary job is the one at which the greatest number of hours were worked.

Demographic characteristics

The survey revealed that between 1980 and 1985, the number of women with two jobs or more rose by almost 40 percent to 2.2 million. Over the same period, the multiple jobholding or "moonlighting" rate for women (percent of employed with more than one job) jumped from 3.8 to 4.7 percent. In 1985, women made up nearly two-fifths of all moonlighters.

Moonlighting among women has actually been rising steadily since 1970, paralleling their continued increase in overall labor force participation. Over the decade and a half, the number of women holding at least two jobs has more than tripled and their moonlighting rate has risen from 2.2 to 4.7 percent. (See table 1.)

The moonlighting rate for men, which had undergone a long-term decline before stabilizing during the 1970's at around 6 percent, continued to hold steady at 5.9 percent in May 1985. While men are still more likely than women to be working at two jobs or more, the gender difference in the incidence of multiple jobholding has been sharply reduced over time. As recently as 1970, the moonlighting rate for men exceeded that for women by 5 percentage points; by 1975, the gap had shrunk to 3 percentage points; by 1980, it had declined to 2 points; and, as shown above, by 1985, it barely exceeded 1 point.

Significant differences still persist, however, in the types of jobs held by the men and women who moonlight. In 1985, about 40 percent of the women were working at multiple part-time jobs, while more than four-fifths of the male moonlighters usually worked full time at their primary jobs and part time on their secondary jobs.

Among men, the proportion holding more than one job increases progressively in each age group, reaching a peak of 7.1 percent in the 35 to 44 years interval and declining

---

John F. Stinson, Jr. is an economist in the Division of Data Development and Users' Services, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

steadily thereafter. Among women the pattern was much different. The proportion holding multiple jobs was 5 percent in all age groups below 45 years and then dropped off progressively. (See table 2.)

While married men were more apt to moonlight than either single men or those who were widowed, divorced, or separated, married women were somewhat less likely to work at more than one job than were those without a spouse.

Whites continued to be much more likely than blacks to work at two jobs or more. In fact, the moonlighting rate for whites increased from 5.1 to 5.7 percent between 1980 and 1985, while the black rate was unchanged at 3.2 percent. The increase for whites was principally among women, whose moonlighting rate rose a full percentage point to 4.9 percent; the rate for white men edged up slightly to 6.2 percent. Hispanic women had a moonlighting rate of 2.8 percent, about the same as that for black women, while the rate for Hispanic men was below that of blacks and only half the rate of white men.

Reasons for working at more than one job

Economic factors predominate among the reasons for moonlighting. About 41 percent of persons working more than one job in May 1985 reported that they did so in order to meet regular expenses or pay off debts, and 13 percent cited a desire to save for the future. Another 17 percent indicated that their principal reason for moonlighting was to get experience or build up a business, while 29 percent reported various other reasons. Women were slightly more likely than men to indicate the desire to get experience in a different field of work. (See table 3.)

Marital status had a clear effect on the reasons reported for moonlighting. Single men and women were more likely than other groups to moonlight in order to accumulate savings for the future. Current financial considerations played a much more important role in the decision to moonlight for widowed, divorced, and separated workers. More than two-thirds of the women and almost half of the men in that category cited either the need to meet regular expenses or to pay off debts as their reason for working at more than one job.

There was also a sharp divergence in the distribution of the reasons for multiple jobholding reported by blacks and whites. Blacks of both sexes were much more likely than whites to say they moonlighted in order to help with regular expenses and paying off debts and much less likely to say they did so to get experience or to build up a business.

Class of worker, industry, and occupation

The proportion of multiple jobholders engaged in farming in either their primary or secondary job—a prominent activity among dual jobholders in the past—declined to fewer than one-tenth in May 1985. In most cases, these workers had primary jobs as wage and salary workers in nonagricultural industries but did some farming on their own. (See table 4.) While the proportion of such workers had been edging down as shown in the following tabulation, the drop between 1980 and 1985 was particularly sharp, undoubtedly reflecting the myriad problems encountered by the farm sector in recent years:

	Total multiple jobholders (thousands)	*With at least one job in agriculture*	
		Total (thousands)	*Proportion*
1970	4,048	943	23.3
1975	3,918	890	22.7
1977	4,558	922	20.2
1979	4,724	871	18.4
1980	4,759	835	17.5
1985	5,730	532	9.3

Table 1. Employed persons 16 years and over holding two jobs or more and multiple jobholding rates by selected characteristics, May 1970 to May 1985

[Numbers in thousands]

Year	Total employed	Multiple jobholders				Multiple jobholding rate[1]				
		Total	Men	Women		Total	Men	Women	White	Black[2]

Unpaid family workers	280	9	3.2	–	–	(2)	9	9	(2)

[1] Self-employed persons with a secondary business or farm, but no wage and salary job, are not counted as multiple jobholders.

[2] Persons whose primary job was as an unpaid family worker are counted as multiple jobholders only if they also had a wage and salary job.

Among the other multiple jobholders—that is, the vast majority who did not engage in any agricultural work—about one-third were self-employed in at least one job, usually the second job. The rest worked as wage and salary employees in both jobs.

The workers whose primary jobs were in industries such as entertainment and recreation services; professional services, especially educational services; and public administration were the most likely to engage in moonlighting. In terms of specific occupations, the men most likely to moonlight were those employed as teachers, both at and below the college level, or as health technologists and technicians. Between 16 and 19 percent of them held a second job. A high proportion of dual jobholders (13.9 percent) was also found among male protective service workers, a group which includes police, who frequently moonlight as guards and security personnel. There were no occupations for women with such high rates of multiple jobholding. The highest rates for women were among officials and administrators in public administration, with a moonlighting rate of 7.5 percent, and health diagnosing occupations; teachers at all levels; and engineering and science technicians, all with rates around 7 percent.

Hours of work and earnings

Multiple jobholders usually worked an average of about 14 hours per week on their secondary jobs. Almost two-thirds worked less than 16 hours, while about 15 percent reported 25 hours or more of moonlighting work. Although blacks are much less likely than whites to hold more than one job, about 20 percent of black moonlighters reported usually working more than 25 hours per week at their second job, compared with about 15 percent of whites.

Combining all jobs, moonlighters worked an average of 51 hours per week in May 1985. The average for men, at 55 hours per week, exceeded by 10 hours that usually worked by women with two jobs or more.

The median usual weekly earnings from all jobs of multiple jobholders (who were wage and salary workers on their primary job)[4] was $343 in May 1985. For women who moonlighted, total weekly earnings from all jobs ($241) were equal to little more than half of the earnings of multiple-jobholding men ($450). The total weekly earnings for black multiple jobholders were $305, slightly below the $344 average for whites.

Looking only at the second jobs, the earnings reported by multiple jobholders yielded a median of $70 in May 1985. Just over three-fifths of the moonlighters reported earnings of below $100 per week for their second job; one-fourth reported between $100 and $200; and about 13 percent reported earnings of over $200 per week. As was generally the case with regard to the principal job, men earned considerably more on the second job—$85 per week—than did women—$57 per week. Three quarters of the women reported weekly earnings of less than $100 on their second job, compared with a little more than half of the men.

Consistent with their greater hours worked, blacks reported earning more on their second jobs than did white moonlighters; the medians for the two groups were, respectively, $81 and $69 per week. Because black workers tend to earn much less in their primary jobs than do white workers, the earnings from secondary jobs help to narrow the income gap between whites and blacks who engage in multiple jobholding. ☐

FOOTNOTES

[1] The data were obtained through special questions asked in conjunction with the May 1985 Current Population Survey (CPS), the monthly survey of about 59,500 households which provides the basic labor force and unemployment data for the Nation. Data on multiple jobholders used to be collected each May in a supplement to the CPS until the supplement was ended after 1980. For the most recently published report on multiple jobholders, see Daniel E. Taylor and Edward S. Sekscenski, "Workers on long schedules, single and multiple jobholders," *Monthly Labor Review*, May 1982, pp. 47–53.

[2] Also included as multiple jobholders are a small number of persons who had two jobs because they changed jobs during the survey week. Persons employed only in private households (such as housekeepers, launderers, gardeners, babysitters, and so forth) who worked for two employers or more during the survey week, are not counted as multiple jobholders because working for several employers is considered an inherent characteristic of private household work rather than an indication of multiple jobholding. Also excluded are self-employed persons with additional farms or businesses and persons with secondary jobs as unpaid family workers.

[3] Included among the wage and salary workers are the incorporated self-employed (individuals who worked for corporations which they owned). The number of dual jobholders in this category is very small (58,000, or 1 percent of all moonlighters) and their inclusion among the wage and salary workers should have a minimal impact on the analysis of the data.

[4] Data on wage and salary earnings only were collected for the primary job. Data on earnings from all sources were collected for the second job.

Missed work and lost hours, May 1985

Absences were lower in 1985 than at any time since 1973; for the first time, absence rates in the goods-producing industries were lower than the rates in the service-producing industries

BRUCE W. KLEIN

On any given day, some people do not show up at work for one reason or another. These unscheduled absences can disrupt the work flow and raise costs such as sick pay and the hiring of temporary help. Absences may also result in a reduction in product quality and low morale among the workers who get additional duties passed onto them.

According to data collected in May 1985 from the Current Population Survey (CPS), about 4.7 percent of the full-time nonfarm workers had an absence in a typical week caused by illness, injury, civic duties, or personal reasons. The proportion of hours lost was 2.6 percent of the potential that would have been worked during the survey's reference week. These absence figures were substantially lower than those last obtained in a 1980 survey. In fact, they showed the first decline since the Bureau of Labor Statistics began estimating absences in 1973.

The proportion of full-time wage and salary workers who had an absence which kept them from working at least 35 hours per week declined by more than 20 percent between May 1980 and May 1985. An absence measure computed by the Bureau of National Affairs from entirely different data has also shown a similar decline over the same period.[1] In addition to a decline in the percent of workers absent from work, the CPS shows that the percent of total worktime lost because of absences also declined by more than 20 percent during the period mentioned.[2] (See table 1.)

The drop in absences during this 5-year period may have stemmed from the aftereffects of the 1981–82 recession. There appear to be two primary reasons for a drop in absences: (1) workers laid off during the recession are likely to have included many of the frequent absentees, and (2) remaining workers were less likely to be absent from their jobs in the aftermath of a recession or during a period of business uncertainty for fear of job loss.[3] In addition, absence rates may have remained low during the economic recovery because of explicit personnel policies on absences. In some cases, various penalties and incentives were put into place to keep them down.[4]

Although there has been a substantial reduction in the frequency of absences and in the proportion of time lost, the number of hours lost per individual worker with an absence increased slightly between 1980 and 1985. Reasons other than illness or injury were responsible for most of the increase.

Absence concepts

The term "absences," as used here, relates to generally unscheduled periods of leave from work. Reasons for absences include illnesses, injuries, personal and civic commitments, and mishaps. For example, car failure is some-

---

Bruce W. Klein is an economist in the Division of Data Development and Users' Services, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

times an excuse for an absence. The data presented here relate only to full-time wage and salary workers, those who usually work more than 35 hours per week and who hold only one job. They are deemed to have been absent by reporting that they worked less than 35 hours per week because of illness, injury, or other reasons.

Absences are measured by rates which identify (1) the proportion of workers with an absence; (2) the proportion of hours lost relative to all scheduled hours; or (3) relative to the hours usually worked by those with an absence. Specifically, the incidence rate is the number of workers absent divided by the total employed times 100 or,

$$\frac{\text{Number of workers absent}}{\text{Total employed}} \times 100 \ .$$

The inactivity rate is the number of hours absent divided by the total number of hours usually worked times 100 or,

$$\frac{\text{Numbers of hours absent}}{\text{Number of hours usually worked}} \times 100 \ .$$

A third measure, the severity rate, indicates the proportion of hours lost by workers with an absence relative to the hours they usually work, also expressed in percentage terms, or

$$\frac{\text{Number of hours lost by absent workers}}{\text{Number of hours usually worked by absent workers}} \times 100 \ .$$

Annual rates and comparisons

Extrapolating from the data gathered for May, it is estimated that because of absences, an average worker lost 7.2 days in 1985, compared with an estimate of 9.7 days in 1980. It is estimated that a typical worker had absences in 3 of 52 weeks during 1985, down from 4 of 52 weeks in 1980.

The absence rate for the United States—4.7 percent—compares favorably with recent percentage rates of the following countries: England (11.8), Canada (11.6), Denmark (7.7), France (5.9), the Netherlands (5.4), Belgium (3.8), Greece (3.1), Germany (3.0), Sweden (3.0), Italy (2.9), and Japan (2.5). The rates for Australia and Ireland are similar to the U.S. rate—4.3 and 5.2, respectively.[5]

Variation by industry and occupation

Differences in absence rates between the various industries and occupations were also significant, as were their trends. In May 1985, for the first time, the absence rates in goods-producing industries were lower than those in service-producing industries. This was true both for the incidence of absences and the measurement of hours lost because of absences. This reversal could reflect a new attitude in goods-producing industries regarding the costs associated with unscheduled work absences. Many companies have instituted various policies to reduce absences, using both "the carrot and the stick." In some instances, they have introduced the practice of giving bonuses to workers with high attendance. They have also counseled workers who are frequently absent before taking more serious steps against them. In part because of these new policies and the other factors cited above, the durable goods industry has achieved especially low absence rates. (See table 2.)

Public administrations have the highest percentage of workers with absences, which may be the result of liberal leave policies towards Federal, State, and local government employees. Businesses which supply professional services also have relatively high rates of absences, both in terms of incidence and inactivity. Within the professional services sector, educational and medical service providers have the highest absence rates. This may reflect the fact that teachers, who make up a large component of this group, usually have an allotment of personal days off which are filled by substitute teachers. Absences are not easily explained for employees of hospitals and other health service providers.

In terms of occupation, the absence rate reported by persons in executive and administrative positions, and those in management-related occupations was relatively low—3.2 percent. This contrasts sharply with the higher incidence of absences for professional specialists, 5.2 percent. These differences, which are also reflected in the proportion of time lost, could be caused by the high degree of competition and visibility among executives and also the fact that some of the professionals, such as teachers, have contracts which allow for a certain number of absences during the year. (See table 3.)

The precision production, craft, and repair occupations

[1] Excludes incorporated self-employed workers.
[2] Includes industries, not shown separately.

NOTE: Detail may not add to totals because of rounding.

have a relatively low incidence rate (4.3 percent). The less skilled group of operators, fabricators, and laborers have a higher incidence rate (5.5 percent). Among the lower skilled workers, handlers, equipment cleaners, helpers, and laborers have the highest absence rate (6.7 percent). These lowest skilled, low-paying jobs are often hazardous and have unpleasant working conditions, for example, fumes, noise, dirt, and heat. Given the gradual shift in technology, a substitution of high skilled manual workers for low skilled may have contributed to the reduction in absence rates.

Variation by personal characteristics

Teenagers have the highest absence rate of any age group, as shown below in the incidence rates for men and women in various age groups:

	Percent of workers with an absence in the reference week, May 1985		
	Total	*Men*	*Women*
All ages	4.8	3.7	6.3
16–19 years	7.0	6.7	7.4
20–24 years	4.8	3.9	5.9
25–54 years	4.6	3.4	6.3
55 years and over	5.7	5.0	6.8

Teenagers may have a higher absence rate because they attach more importance to nonwork activities than do older workers. As workers get into their early twenties, their absence rates decline and approach that of workers age 25 to 54. Past age 55, the absence rate rises again for both men and women. Health problems and health maintenance needs may affect this increase.

For women, the absence rate increases in their prime years, while for men, the rate falls. Understandably, women have a higher incidence of absences during their childbearing years, especially women with children under age 6. However, men with children have a relatively low absence rate. (See table 4.) Marital responsibilities seem to induce men toward a firmer commitment to their jobs, so that they spend less time away from work. For most women, the proportion of time lost increased with the presence of children, especially young ones. Women maintaining families alone who have three children or more have the highest absence rate. This may be because these women have no one to fall back on when their children need care during their working hours. Other family-related responsibilities, such as care of other family members, may be another factor in their relatively high absence rates.

ABSENCE RATES DROPPED considerably between 1980 and 1985. This is probably caused by the fallout from the recession of 1981–82 when workers with attendance problems may have been dismissed in greater numbers. This, in turn, may have induced fear of job dismissal in other workers who kept their absences low. Cost-cutting measures have also

Table 3. Absence rates for full-time wage and salary workers, by occupation, May 1985

NOTE: Detail may not add to totals because of rounding.

caused employers, particularly in manufacturing, to institute various means to hold absences down, both through incentives and disciplinary action. Reflecting these trends, the absence rates in the goods-producing sector were lower in 1985 than those in the service-producing sector, a situation that has not been observed before, at least not since 1973. ☐

Measures to increase incomes

The vital role of women in agriculture in many parts of the developing world means that they should be assisted in rural development programs, for example, by the introduction of appropriate technology and simple farm tools to reduce the burden of their work on the land and in the home. Technological innovation and appropriate training aimed at peasant and small-holder farmers should be organized as part of extension services which are easily accessible to even the poorer segments of the rural population. The adoption of appropriate technologies will be crucial to the attainment of food self-sufficiency in the coming decade, and here again is a field in which the ILO has an important role to play in the coming years, building on experience gained so far. Other policy measures to increase agricultural production deserving of consideration include the provision of infrastructural facilities and essential public services (for example, roads, irrigation, health centers, schools); improved access to credit; and pricing and marketing policies appropriate to the maximization of the growth of output and employment in rural areas.

Work at home: new findings from the Current Population Survey

In May 1985, more than 8 million Americans reported at least 8 hours per week of home-based work; services, ranging from consulting to child care, were the most common pursuits of persons working substantial numbers of hours at home

FRANCIS W. HORVATH

For some Americans, there is no separation of gainful work between the home and the workplace. A large number of persons regularly squeeze extra hours into their workweek by performing job-related chores at home. Others have completely eliminated the trip to work by setting up businesses or performing work-for-hire while at home.

In May 1985, the Bureau of Labor Statistics made its first attempt to determine the size of the home-based work force. Along with other questions on work practices, the respondents to the May survey were asked whether: "As part of . . . (the worker)'s regularly scheduled work, does . . . (he/she) do any of (his/her) work for . . . (the principal employer) at home?" Persons answering affirmatively were asked to estimate the number of hours of work done at home.

While more than 18 million people responded affirmatively, almost half of them worked at home for less than 8 hours a week. Another 770,000 were farmers or farm laborers. The remainder, nearly 8.4 million persons, had worked at home for 8 hours or more in the reference week, as part of a nonfarm job. They are the focus of most of the analysis which follows.

It should be noted that persons working at home on a second job or business were not counted among home-based workers. "Work-at-home" as defined here pertains only to work done as part, or as an extension, of one's primary job. Of course, given this definition, it is possible that persons who regularly bring work home, such as managers reading or writing memos at home, or teachers grading papers, might consider such work to be "regularly scheduled," and will report it as home-based work.

Earlier studies

The May survey was the first specific attempt to estimate the size of the home-based work force. Other estimates had been available from secondary sources and private studies.[1] For example, in response to a special congressional request, the Census Bureau had produced a tabulation on persons working at home from the data gathered as part of the 1980 census.[2] The specific source for the study was a question on methods of travel to work, to which one possible response was "worked at home." According to the data, about 2.2 million persons were identified as home-based workers. More than half (1.2 million) of homeworkers were self employed.

More recently, a privately conducted study was designed to study work-at-home styles. In a telephone survey, respondents were asked questions about work hours, job satisfaction, and computer usage in the home. Nearly 60 percent of the respondents cited working part-time at home as the "ideal work arrangement."[3]

Francis W. Horvath is an economist in the Division of Data Development and Users' Services, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

Who are 'homeworkers'?

Of the 17.3 million persons with any home-based work in nonfarm occupations (regardless of the number of hours reported), about 9.6 million (55 percent) were men. (See table 1.) While men outnumbered women in the general classification of home-based work, women who worked at home had a stronger commitment to the home as a workplace. For example, women averaged 11.1 hours per week on home-based work, while men put in 9.3 hours. About 8 percent of the women worked 35 hours or more at home, compared with 4 percent of the men. Overall, there were 60 percent more women than men who worked the equivalent of a full-time week at home.

Work at home appears to be a particularly attractive option for older persons, for whom the daily commute to work can be very tiring. Nearly one fifth of all nonfarm home-based workers working 35 hours or more weekly consisted of persons over 55 years of age, a group that accounts for only 1 in 8 of all employed workers.

The distribution of home-based work by race also showed slightly higher percentages of white workers than are found in the overall labor force. There were about 660,000 black and Hispanic workers with 8 hours or more of home-based work.

Industrial and occupational comparisons

Much of the interest in home-based work has centered around a few key industries and occupations. For example, it is believed that a growing number of clerical workers are opting to establish their own businesses at home, having been attracted by the idea of "being one's own boss."[4] Clerical workers such as secretaries, typists, forms processors, and data entry personnel have seen a drop in the cost of capital equipment that has enabled them to set up shop at home. Declining prices for personal computers and other electronic equipment have given many persons in professional service industries, such as financial records processing and bookkeeping, an opportunity to begin a business with very low startup costs.

Table 1. Employed persons working at home, by age, sex, and hours worked at home, May 1985

[Numbers in thousands]

[1] Excludes forestry and fisheries.

Table 2 presents counts of home-based workers who worked for 8 hours or more at home by major nonagricultural industry group and sex. By far the largest industry group of home-based workers is in services. This category includes educational, professional, and business and repair services, as well as such social services as child care. Nearly 60 percent of women who worked 8 hours or more at home were in the services industry, compared with only 35 percent of the men.

The longer an individual's weekly hours of home-based work, the more likely he or she is to be engaged in a services industry. More than half of men and two-thirds of women in nonagricultural industries with long hours of home-based work were in service industries.

A more detailed look at home-based work in services is presented in table 3. Business and repair services accounted for nearly 100,000 of the persons working full-time workweeks at home. This category includes a variety of establishments, such as business management and consulting services and computer and data processing services. Social services, which encompass child care, accounted for 110,000 full-time home-based workers. Another 90,000 home-based workers were in "other professional services," covering legal services, architectural services, religious organizations, and others.

Table 3 also presents counts by class of worker. It shows that among the universe of persons with 8 hours or more of home-based work in the reference week, the majority were private wage and salary workers, who may simply be bringing work home on a regular basis. However, among those

Table 3. Employed persons in the services industry with 8 hours or more of home-based work, by class of worker, May 1985

NOTE: Dash indicates zero or rounds to zero.

who worked 35 hours or more, close to 70 percent were self-employed in home-based, unincorporated businesses. Fewer than 10 percent of all full-time home-based workers were self-employed but incorporated.

It is not possible to determine from the May 1985 data how many persons working at home use a computer in their work, or how many persons "telecommute" to their jobs.[5] No specific questions on this topic were asked as part of the survey supplement. However, some insight about the effects of technological change on work practices can be gained by examining the distribution of home-based work by occupation. (See table 4.) One of the largest occupational groups of home-based workers is in "financial records processing." This category includes bookkeepers, accountants, and auditors, as well as persons operating billing, posting, and calculating machines.

Table 4. Employed persons working at home, by major and selected nonfarm occupations and hours worked at home, May 1985

[Numbers in thousands]

Personal services	592	569	462	243	27.3

[1] See footnote 1, table 1.

The ranking of some occupations by incidence of home-based work might be surprising. This may be related to the fact that the May 1985 survey measured those who bring work home as well as those who have formally set up a home-based workplace. The difference between merely bringing some work home and doing all or most of one's work at home is often reflected in the number of hours worked at home. For example, teachers, who might grade papers or prepare lectures at home, accounted for 1.3 million of the 8.4 million nonfarm workers with 8 or more hours of such work, but virtually none of the teachers accumulated 35 or more hours at home. Similarly, while almost 40 percent of all employed managerial and professional specialty workers reported regular homework, only 270,000 of them accumulated full-time workweeks while at home. As noted earlier, a very large proportion of those with 35 or more hours of home-based work were in service occupations, and in particular, personal services.

Formalized arrangements rare

In standard classifications, the Bureau of Labor Statistics divides employed workers into three class-of-worker categories—wage and salary, self-employed, and unpaid family workers. For purposes of comparability with the Bureau's establishment data, those workers who are the nominal employees of corporations which they own—the "self-employed incorporated"—are treated as wage and salary workers. In our analysis, however, these workers are displayed separately, leaving an "all other wage and salary workers" category that consists entirely of persons employed by someone else.

Table 5 displays a breakdown of home-based workers according to this classification. It suggests that formalized business arrangements are rare for the typical home-based worker. Fewer than 7 percent of those working full time at

Table 5. Percent distribution of employed persons with 8 hours or more of home-based work, by class of worker and sex, May 1985

Class of worker	Total		Men		Women

NOTE: Dash indicates zero or rounds to zero

home in nonagricultural jobs were incorporated. For agriculture and nonagriculture combined, about 2 of every 3 home-based workers who worked 35 hours or more were operating as unincorporated self-employed businesspersons.

Children and home-based work

Home-based work offers a chance for some persons with children to more effectively combine the roles of parent and worker. Elimination of commuting and child-care expenses can be a strong incentive for households with young children to experiment with home-based work. About 600,000 married mothers of children under 6 years of age reported some home-based work. (See table 6.) More than one-fifth of such women worked at home for 35 or more hours as part of their contribution to the job market.

In general, there were slight differences between women and men working in homes with young children. However, among nonfarm workers with 35 hours or more of home-based work, there were three times as many women with very young children as there were men.

Working exclusively at home

Using responses from the regular portion of the Current Population Survey as well as those from the May supplement, it is possible to compare the hours worked at home with all work hours during the previous week and thus identify persons working "entirely" at home. The classification showed 2.2 million persons working exclusively at home in May 1985. (See table 7.) About 390,000 of those working exclusively at home were in farming occupations, leaving almost 1.9 million persons as the home-based work force. About two-thirds of these were women.

As might be expected, the hours of persons working solely at home were far higher than the overall averages for home-based work. Where work was conducted exclusively within (or from) one's home, men averaged 41.1 hours, while women totaled 27.7 hours. About half of the persons whose work was entirely home based were in service industries, such as professional services, business and repair services, and personal services. Only about 100,000 of the persons with home-based work in professional specialty occupations, which includes computer programming as a subset, worked entirely at home.

Restricted industries

In the 1940's, following a series of public hearings, the Labor Department moved to restrict home-based work in a number of narrowly defined industries. This recently criticized and reevaluated "patchwork" of regulations was directed toward those activities which had been found to be in violation of the Fair Labor Standards Act. The seven industries were: women's apparel, jewelry, gloves and mittens, knitted outerwear, buttons and buckles, handkerchiefs, and embroidery. Homework in those industries was permitted for individuals meeting specific certificate requirements. The recent arguments surrounding home-based work have crystalized around these apparel and accessory industries.[6]

The May 1985 data do not allow an accurate determination of the number of persons whose home-based work is in the various restricted industries. The industrial classification used in tabulating these data no longer coincides with the 1940's-based industry definitions upon which the restrictions were based. Some of the restricted industries extend across multiple classifications in the current data, or fall into a highly aggregated "all other" category, which includes industries in addition to the restricted one. However, it is possible to create an upper-bound estimate of the total number of persons affected by the restrictions by adding up workers in every detailed industry classification which overlaps with the restricted industries. Using the finest available breakdown of industries,[7] it was estimated that the maximum number of persons working 8 hours or more at home in restricted industries could not exceed 125,000, and the number working 35 hours or more was below 20,000. About

[1] Data not shown where base is less than 75,000.

90,000 of these persons were in either the apparel industry—which includes both restricted and unrestricted work—or the jewelry industry. The total was evenly divided among men and women. Because this was the first time this survey has been conducted, it is not possible to determine if this number of homeworkers has been increasing or decreasing. ☐

Overtime work: an expanded view

More comprehensive survey covers overtime hours even of persons who do not exceed the traditional 40-hour week; 1.6 million of them received premium pay in 1985

DARRELL E. CARR

About 10 percent of all American workers received overtime pay for hours worked in a typical week in May 1985. The great majority of them worked more than the traditional 40 hours that week; however, some received overtime pay even though their workweek did not exceed 40 hours.

Prior to 1985, data on overtime work were limited to employees who worked more than 40 hours a week at a single job.[1] In addition to these data, the May 1985 Current Population Survey also collected information on overtime work performed by persons with 40 or fewer hours of work in the reference week. An additional feature of the 1985 data is that they are not limited to persons holding only one job.

There were several reasons for extending the survey questions on overtime to workers with 40 or fewer hours of work in a week. First, these workers constitute a majority of those in wage and salary jobs.[2] The following tabulation shows the distribution of wage and salary workers, by hours, May 1985 (numbers in thousands):

Total, all schedules	90,892
41 hours or more	24,386
40 hours or fewer	66,506
40 hours	38,477
39 hours or fewer	28,028

Second, in some jobs, by custom or agreement, the standard full-time workweek is well below 40 hours. Finally, regardless of the length of the workweek, some workers receive overtime pay for working more than a set number of hours per day. The inclusion of these additional workers in the analysis of overtime pay sheds new light on the topic.

Why use overtime?

There were 10.5 million persons with some overtime work in the reference week for the May 1985 survey. They labored an average of 9 hours at premium rates (generally time-and-one-half), for a total of about 94 million hours. Thus, the total dollar costs of such premiums to employers ran into millions. Why would employers incur these additional expenses?

Over the very short term, employers use overtime hours to fill rush orders, to meet seasonal peaks in demand, and to maintain production schedules despite employee absences and mechanical failures. But overtime work is also used when employers are unable to hire workers with critical skills, or when they are simply reluctant to hire new workers because of uncertainties over future product demand and the labor requirements that go with it.

Some employers may even schedule overtime work on a regular basis, rather than hire additional workers, even when workers are readily available and product demand is fairly constant. Employers tend to use this approach, according to Ronald G. Ehrenberg, when they perceive the costs of overtime premiums to compare favorably with the quasi-fixed employee-related expenses—such as sick leave, annual vacations, paid holidays, health insurance, and pension funding—which they would incur if they expanded their payrolls.[3]

Darrell E. Carr is an economist in the Division of Data Development and Users' Services, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

Does the use of overtime keep unemployment higher than it would otherwise be? In this regard, it should be noted that the framers of the Fair Labor Standards Act of 1938 believed that overtime work reduced the number of new hires, thereby keeping individuals jobless and general unemployment levels high. Therefore, they incorporated a provision into the Act which required time-and-one-half pay for all hours worked in excess of 40 a week in covered jobs. This measure was clearly designed to discourage the use of overtime, to encourage the hiring of more workers, and thus to reduce unemployment.[4]

Table 1. Total wage and salary workers, those who received overtime pay, and the rate of pay received, by selected characteristics, May 1985

[Numbers in thousands]

[1] Data refer to wage and salary workers, excluding the incorporated self-employed, who were at work during the survey week.

[2] Includes a small number of persons who did not report the number of overtime hours paid or the rate of pay received.

NOTE: Detail for race and Hispanic-origin groups will not sum to totals because data for the "other races" group are not presented and Hispanics are included in both the white and black population groups.

During the early sixties, the causal relationship between overtime and unemployment was asserted again. The *1964 Economic Report of the President* linked the heavy use of overtime in some industries with curtailed job opportunities, and proposed legislation that would increase the premium rate for overtime work from time-and-one-half to double-time.[5] However, the proposed legislation was not enacted.

Some economists, in the meantime, have played down the impact of overtime work on unemployment. For example, Ehrenberg found, first of all, that an overtime rate of time-and-one-half was not a sufficient penalty to deter employers from using overtime instead of hiring new workers, particularly where the fringe benefit costs (fixed costs not related to hours worked) are comparably high. Second, he calculated that while an increase in overtime rates to double-time would further reduce overtime hours, the reduction would not translate into a significant decline in the level of unemployment.[6]

In a 1977 followup study, which expanded upon Ehrenberg's earlier work on the effect of overtime on unemployment, Joyce Nussbaum and Donald Wise concluded: "Both theoretical and statistical analysis confirmed the hypothesis that an increase in the overtime premium would cause a reduction in average annual overtime hours. However, the hypothesis that this reduction in overtime hours would be compensated for by a commensurate increase in employment was not supported."[7]

These researchers also concluded that the increase in the number of jobs that would result from lifting the overtime rates from time-and-one-half to double-time would be small. They noted that the increase in the potential gains in jobs must be weighed against other consequences—lower income for the persons previously working overtime, a possible reduction in output, and a rise in prices.[8]

Who works overtime?

Men, 25 to 34 years of age, are the workers most likely to put in extra hours at overtime rates. Nearly one-fifth of them, regardless of the total number of hours they reported, had been paid some overtime premiums for work performed in the reference week. (See table 1.) Women were about half as likely as men to report paid overtime work.

Age and marital status also play a role in one's probability of working at overtime rates. Among both men and women, the likelihood of working overtime was relatively low for workers in the 16- to 24-year-old group, increased for the 25- to 34-year-old group, and declined progressively thereafter for each age group. The effect of marital status on the probability of working overtime was different for men and women. Married men were more likely to work overtime than single men. For women, the situation was reversed: married women, probably because of their household responsibilities, were less likely to work overtime than single women. Actually, the women most likely to work overtime were those in the "divorced, widowed, or separated" group. (See table 1.)

Table 2. Total wage and salary workers, those who received overtime pay, and the number of overtime hours paid, by occupation and industry, May 1985

[Numbers in thousands]

Occupation and industry	Total wage and salary workers[1]	Received overtime pay		Percent receiving overtime pay for —		
		Number[2]	Percent	1 to 8 hours	9 to 15 hours	16 hours and over

[1] Data refer to wage and salary workers, excluding the incorporated self-employed, who were at work during the survey week.

[2] Includes a small number of persons who did not report the number of overtime hours paid.

Whites were somewhat more likely to work at overtime rates than blacks or Hispanic origin workers. But, regardless of race or Hispanic origin, women were only half as likely as men to work overtime.

Occupation and industry. Among the various occupational groups, the highest proportion of workers reporting some work at overtime rates was in the precision production, craft, and repair group. About 22 percent of the 11.1 million members of this group had received premium rates for some of the hours worked during the May 1985 survey week. (See table 2.) Following closely behind at 20.7 percent were operators, fabricators, and laborers. Together, these two occupational groups accounted for more than half of the 10.5 million workers with some overtime earnings.

The proportion of workers with overtime earnings was much smaller among other occupational groups. For example, of the workers in the managerial and professional specialty occupations, only 6 percent reported paid overtime work. For the most part, these occupations are exempt from the overtime pay provisions of the Fair Labor Standards Act which, as of 1983, applied to an estimated 56 million nonsupervisory jobs.

In terms of industry concentration, overtime work was most common in mining, where 27 percent of the workers reported receiving premium pay in May 1985. In manufacturing, the proportion was 20 percent. Although fewer than

Table 3. Total wage and salary workers, those who received overtime pay, and the number of overtime hours paid, by length of the workweek, May 1985

[Numbers in thousands]

Length of the workweek	Total wage and salary workers[1]	Received overtime pay		Percent receiving overtime pay for —			Mean overtime hours paid
		Number[2]	Percent	1 to 8 hours	9 to 15 hours	16 hours and over	
Total, 16 years and over	90,892	10,528	11.6	63.8	21.8	14.3	9.0
Worked 41 hours or more	24,386	8,926	36.6	60.4	23.6	16.0	9.6
On one job	21,421	8,416	39.3	60.3	23.5	16.2	9.6
On two jobs or more	2,965	510	17.2	62.1	25.6	12.4	9.6
Worked 40 hours or fewer	66,506	1,601	2.4	83.3	11.7	5.0	6.0
Worked 40 hours	38,477	880	2.3	79.4	14.6	6.0	(3)
Worked 39 hours or fewer	28,026	722	2.6	87.8	8.2	4.0	(3)

[1] Data refer to wage and salary workers, excluding the incorporated self-employed, who were at work during the survey week.

[2] Includes a small number of persons who did not report the number of overtime hours paid.

[3] Not available.

one-fifth of all workers are now employed in manufacturing, the industry accounted for about two-fifths of those with paid overtime work in May 1985. The construction industry also had a relatively high proportion of workers (15.8 percent) reporting some overtime earnings. In contrast, in agriculture and such industries as finance, insurance, and real estate, government, and services, the proportion of employees with overtime work did not exceed 10 percent, and was generally much lower.

Hours worked. As might be expected, the great majority of persons receiving some overtime pay worked more than the 40-hour standard workweek. The following tabulation shows the number of wage and salary workers by hours worked and by the number and proportion receiving some overtime pay, May 1985 (numbers in thousands):

		Received overtime pay	
	At work	*Number*	*Percent*
Total, all schedules	90,892	10,528	11.6
Worked 41 hours or more	24,386	8,926	36.6
Had one job only	21,421	8,416	39.3
Had two jobs or more	2,965	510	17.2
Worked 40 hours or fewer	66,506	1,601	2.4

About 24.4 million persons reported having worked more than 40 hours in the May 1985 survey week. The great majority of these workers (21.4 million) worked at only one job. Our major interest—and the concern of the Fair Labor Standards Act—lies with this group. About two-fifths of them reported they had received overtime pay. This is about equal to the percentage of workers with overtime pay found in previous surveys of workers on long workweeks. As for the other three-fifths—those working more than 40 hours but not receiving any overtime pay—they appear to be largely in jobs which did not fall under the provisions of the Act. They were concentrated in managerial, professional, technical, sales, and administrative support jobs, where the payment of overtime premiums for hours worked in excess of 40 is not widely practiced.

The workers receiving premium pay for having labored beyond the 40-hour standard reported an average of 9.6 hours of overtime work. (See table 3.) Nearly two-thirds of them had put in 8 hours or fewer of overtime work. Of the remainder, most reported 9 to 15 hours of overtime; only a small minority—16 percent—reported 16 hours or more.

Even fewer hours of overtime were put in by those reporting the receipt of overtime pay even though their workweek had not exceeded the 40-hour standard. These persons worked an average of 6 hours at overtime premiums. More than four-fifths of them reported 8 or fewer hours for which they had collected overtime pay.

Time-and-one-half was by far the predominant rate of pay for overtime work in 1985. In fact, of the 10.5 million workers with some overtime earnings in the May survey, about 9.5 million, or more than 90 percent, said they were paid "time-and-one-half." Only about 200,000 reported receiving "double-time." Of the remainder, some reported a "graduated rate," but most responses were combined into an "all other" category. □

Preferred hours of work and corresponding earnings

Most workers are satisfied with the number of hours they currently work, although about 1 of 4—especially young people and low earners—would prefer more hours and more money; very few would trade income for leisure time

SUSAN E. SHANK

If given a choice of working the same, fewer, or more hours at the same rate of pay, most employees would prefer the same number of hours. An additional one-fourth would prefer to work more hours and earn more money, while 8 percent would choose to work fewer hours and earn proportionately less money. This finding that well over half of all workers are satisfied with their present hours and pay is based on information obtained from a new question on the May 1985 supplement to the Current Population Survey (CPS), and is consistent with results obtained from similar questions asked by Katona and others in 1966 and by Louis Harris and Associates in 1978.[1]

The degree of satisfaction with current hours and pay rises steadily with age. It is also positively related to the number of hours worked and the weekly earnings level. The "more hours and more money" option appeals especially to young people, many of whom are working only part time, and its popularity declines steadily with age. A large proportion of minority workers, especially men, would also prefer to work more hours and earn more money.

Very few employed persons wanted to work fewer hours and earn correspondingly less money. However, women were more likely than men to prefer reduced hours, even though it meant lower earnings. Also, the proportion choosing this alternative increased with age to a peak in the 35- to 44-age group.

The new CPS question asked for employee preferences on hours of work and corresponding earnings—given the same rate of pay. This question was last on the supplement because it differs significantly from other labor force questions, which focus on a person's activity and emphasize much more objective behavior. The question asked:

> If you had a choice, would you prefer to work:
>
> The same number of hours and earn the same money? .... ○
>
> Fewer hours at the same rate of pay and earn less money? .... ○
>
> More hours at the same rate of pay and earn more money? .... ○

Interviewers asked this question directly of the respondent—unlike other questions where a responsible person in the household could respond for all other household members. Self-response was required because preference is inherently individual and subjective. As a result, information was not obtained for approximately 22 percent of all employed persons. Nonresponse was higher for men than for women, and was substantially higher for teenagers and young adults than for persons age 25 and over. These were

---

Susan E. Shank is an economist in the Division of Employment and Unemployment Analysis, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

the persons less apt to be at home during the day and early evening hours when most interviews are conducted.

In spite of the difficulty in contacting individual respondents, answers were obtained from 8 of 10 wage and salary workers age 25 and over. In this article, distributions of persons wanting the same, fewer, or more hours and corresponding pay are based on the total who reported such preferences. Also, the data pertain only to wage and salary workers (excluding incorporated self-employed persons).

Although the following sections analyze workweek preferences separately by various demographic and job characteristics, it is important to note that many of these characteristics tend to occur simultaneously. For example, young people often work relatively few hours at low rates of pay and express a strong preference for more hours and more money. It should also be noted that preferences about work hours are already reflected, to some degree, in the jobs workers currently hold. This is particularly true for experienced adult workers who presumably have more control over their work schedules than do young people. The analysis of preferences by actual hours at work and by earnings focuses on the 25- to 54-age group in order to exclude those age categories where transition into and out of the labor market have a major impact on hours.

Effect of worker and job characteristics

Preferences about hours and pay differed by age and gender, as well as by present earnings level and actual hours worked. Correlations between workweek preferences and various worker and job characteristics were generally in the expected direction, although some of the magnitudes were surprising. For example, as weekly earnings rose, so did both the proportion of workers expressing satisfaction with their current schedules and the proportion opting for fewer hours and less money. However, it is noteworthy that relatively few men expressed a preference for fewer hours and less pay. Even among those who earned $1,000 or more per week, only 10 percent selected this alternative.

Age and gender. Almost two-thirds of all workers expressed satisfaction with their present hours and pay. This proportion rose steadily with age—from about 40 percent in the teen years to 80 percent for workers 55 and over. (See table 1.) Many older workers, especially those age 65 and over, voluntarily work part time, which contributes to the high degree of satisfaction with their present workweek.

While the proportion wanting to work the same hours increased with age, the percentage desiring more hours moved in the opposite direction. Slightly more than half of

Table 1. Workweek and pay preference of employed persons by selected characteristics, May 1985

[Numbers in thousands]

Characteristics	Total	Reported preference				Did not report preference

All other workers[1]	9,768	7,504	66.1	8.9	25.0	2,264

[1] Includes the self-employed (unincorporated) and unpaid family workers.

NOTE: Detail for the above race/Hispanic-origin groups will not sum to totals because data for the "other races" group are not shown and Hispanics are included in both the white and black groups.

the teenagers—many of whom work part time at low wages—said they wanted more hours and pay, but relatively few older workers wanted more hours. These differences reflect factors such as older persons' greater control over their work schedules, their higher earnings, and less desire for change.

The proportion preferring fewer hours and less pay was small in all age groups. Of the minority who wanted to change their schedules, more hours were preferred 4 to 1 over fewer hours. Only 4 percent of all workers under age 25 would like the fewer hours alternative. Even in the central age groups, where this option was most popular, fewer than 10 percent preferred it.

Women were more likely than men to prefer fewer hours and less pay. In the 25- to 54-age group, where child care and other household responsibilities are greatest, about 10 percent of the women and 6 percent of the men wanted fewer hours. The proportion of women preferring this option then declined to about 7 percent in the 55 and over age group. In contrast, the proportion of men wishing to work fewer hours rose with age until the mid-thirties, but then held steady at about 7 percent for subsequent age groups.

Men preferred to work longer hours somewhat more frequently than women. This difference was most evident in the young adult years, when household formation and spending for consumer goods is high. However, the proportions preferring to work more hours declined with age, and in the 45 and over age groups were virtually the same for women and men. In fact, for older workers there was little difference between the preferences of men and women. Approximately 80 percent of all workers 55 years and over were satisfied with their hours; about 13 percent preferred longer workweeks, while 7 percent opted for fewer hours.

Whites, blacks and Hispanics. Satisfaction with current hours and pay was greater for whites than minorities, with this difference most apparent among men. (See table 1.) The relatively low satisfaction level for both blacks and Hispanics is associated with high proportions wanting more hours and more money. Approximately 4 of 10 black and Hispanic men said they would prefer more hours, compared with about 3 of 10 white men. The fewer hours and related paycut option was selected by only 4 percent of all black and Hispanic workers, whereas about 8 percent of whites made this choice.

Table 2. Workweek and pay preference of 25- to 54-year-old wage and salary workers, by actual hours at work, May 1985

[Percent distribution]

Hours at work	Reported preference		
	Same hours, same money	Fewer hours, less money	More hours, more money
1 to 14	50.9	4.6	44.5
15 to 29	57.3	5.6	37.1
30 to 34	58.6	8.0	33.4
35 to 39	65.0	8.1	26.9
40	70.5	7.1	22.5
41 to 48	65.3	8.1	26.6
49 to 59	66.5	10.8	22.7
60 and over	63.9	16.3	19.8

NOTE: Data exclude incorporated self-employed workers.

Table 3. Workweek and pay preference of wage and salary workers, by occupation and industry, May 1985

[Percent distribution]

Occupation or industry	Same hours, same money	Fewer hours, less money	More hours, more money
Occupation			
Managerial and professional specialty	72.3	9.7	18.0
Technical, sales, and administrative support	66.1	8.3	25.6
Service occupations	56.6	4.5	38.9
Precision production, craft, and repair	63.5	6.4	30.1
Operators, fabricators, and laborers	59.4	5.6	35.0
Farming, forestry, and fishing	49.4	5.0	45.6
Industry			
Agriculture	49.4	7.3	43.3
Nonagriculture	64.8	7.3	27.8
Mining	66.3	8.0	25.6
Construction	58.6	5.3	36.1
Manufacturing	66.7	7.5	25.8
Transportation and public utilities	68.7	7.8	23.5
Wholesale trade	66.3	7.4	26.3
Retail trade	56.3	6.4	37.3
Finance, insurance, and real estate	68.6	8.0	23.5
Services	65.6	7.8	26.5
Public administration	72.3	7.2	20.5

NOTE: Data exclude incorporated self employed workers.

Hours worked. The proportion preferring the same hours and the same money increased steadily with hours actually worked up through 40 hours; it then turned downward. (See table 2.) As would be expected, the fraction wanting more hours and more money fell as hours worked rose—but again only through 40 hours. The changes in preference patterns at the 40-hour and 41- to 48-hours categories are somewhat surprising. The peak in satisfaction at 40 hours may reflect widespread acceptance of the traditional 40-hour workweek, while the monetary influence of the initial hours paid at premium rates, which many workers receive after 40 hours, may explain the small increase in the more hours response. In any case, the proportion wanting more hours declined again when actual hours reached 49 to 59 per week, and fell further (to about 20 percent) for those working 60 hours and over. In contrast, the fraction preferring fewer hours rose with actual worktime up to 35 to 39 hours; it then dipped at 40 hours before resuming its uptrend. However, even when the workweek was 60 hours or more, the proportion preferring more hours was larger than that preferring fewer hours.

Occupation and industry. The pattern of workweek preferences differed sharply across occupations, but variations were smaller among industry groups. (See table 3.) As would be expected, satisfaction was greatest among highly educated and well paid managerial and professional workers. These occupations also scored relatively high on the fewer hours choice and low on the more hours option.

Satisfaction with the current workweek and pay was less common among semi- and low-skilled manual workers and in the service occupations. Only about half of the helpers and laborers, and farming, forestry, and fishing workers wanted to keep the same hours. Here again, low satisfaction with the status quo correlated with a high preference for more hours. The latter alternative was picked by between 40 and 45 percent of the service workers, helpers and laborers, and those in farming, forestry, and fishing occupations.

Public administration was the industry with the highest proportion of workers preferring their current hours, and agriculture was the lowest. Satisfaction was also relatively low in retail trade, where the average workweek is short, and in construction, where hours of work are often irregular. Approximately 4 of 10 workers in retail trade, construction, and agriculture wanted more hours. However, in public administration only 2 of 10 preferred a longer workweek.

Work-leisure tradeoffs

The data on preferred hours of work may be used to examine the effect of income on tradeoffs people make between work and leisure.[2] According to labor supply theory, individuals decide how many hours to work based on their preferences for leisure versus all other goods and services. The wage rate represents the amount of consumption goods that can be obtained per hour worked. As the wage rate rises, two opposing effects are brought to bear on the hours decision.[3] *The substitution effect* leads to a decrease in leisure consumed and an increase in hours worked because leisure time costs more in terms of earnings forgone. In contrast, *the income effect* causes hours of work to fall because at the higher income associated with the higher wage rate, individuals will want to purchase more goods generally, including leisure.

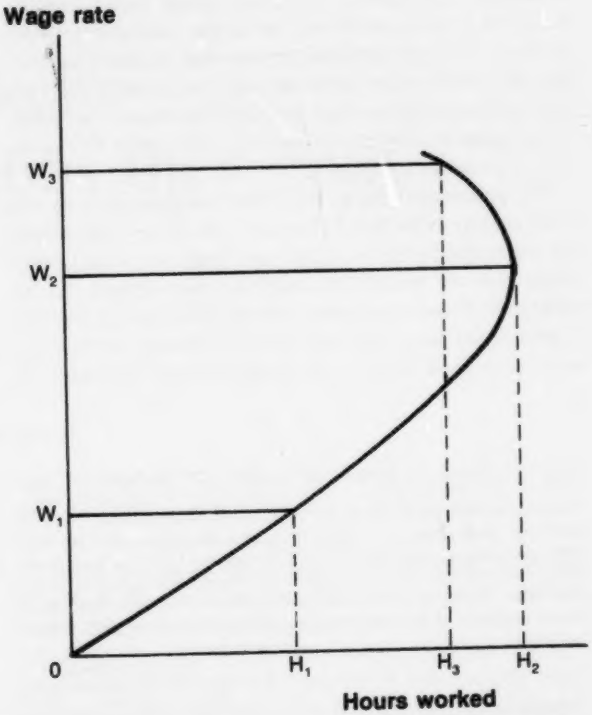
Table 4. Workweek and pay preference of 25- to 54-year-old wage and salary workers, by sex and earnings, May 1985

[Percent distribution]

Weekly earnings	Same hours, same money	Fewer hours, less money	More hours, more money
Men, total	65.5	6.5	28.0
Less than $150	39.3	3.9	56.7
$150 to $199	43.9	3.4	52.7
200 to 249	55.6	4.2	40.2
250 to 299	60.8	2.9	36.3
300 to 399	62.6	7.0	30.5
400 to 499	66.6	6.5	26.9
500 to 599	71.9	7.9	20.3
600 to 749	73.0	7.8	19.1
750 and over	76.6	8.9	14.5
Women, total	67.2	10.9	21.9
Less than $150	55.6	5.0	39.4
$150 to $199	66.6	7.4	25.9
200 to 249	66.6	12.2	21.2
250 to 299	66.2	14.1	19.7
300 to 399	72.6	11.9	15.5
400 to 499	75.7	12.4	11.9
500 to 599	72.0	15.2	12.8
600 to 749	73.2	13.9	12.9
750 and over	63.6	22.0	14.6

NOTE: Data exclude incorporated self-employed workers.

The interaction of these two effects determines whether more or fewer hours of labor will be supplied when the wage rate rises. Both the substitution and income effects are evident in the backward-bending labor supply curve illustrated below:



The lower part of the curve is positively sloped, meaning that at lower wages, labor hours supplied increase as the wage rises. However, above a certain wage rate *(W_2)*, the curve may begin to bend backward, as the income effect dominates.

May 1985 data on preferred hours by earnings suggest some indirect support for the backward-bending supply curve theory.[4] As earnings rise to high levels for prime working-age adults, smaller proportions want to increase their workweeks and larger fractions prefer to decrease their hours of work.[5] (See table 4.) This finding could reflect a strong income effect—causing workers with the highest earnings to want to reduce their work hours—as occurs on the negatively sloped part of the backward-bending supply curve. It could also indicate that workers with lower weekly earnings also have shorter workweeks and are more likely to want to increase, rather than decrease, their hours. Moreover, it is important to note that for men—even men earning $750 or more per week—the proportion wanting more hours of work exceeded that wanting fewer hours.

Women are more willing than men to forgo income for leisure. This was evident at virtually all earnings levels—especially in the prime working-age groups. (See table 4.) About 1 of 8 women earning $200–$499 per week would prefer to work fewer hours. Moreover, when weekly earnings reached $500 or more, the proportion preferring fewer hours was greater than that wanting more hours. No other worker group studied displayed this preference pattern. In the highest earnings category, about one-fifth of the women expressed a preference for shorter hours (more leisure), while only one-seventh wanted longer workweeks (more income). It is also interesting to note that women's satisfaction with their current hours increased as earnings rose only up to a point. Once earnings reached $300 or more per week, the proportion satisfied leveled off, and it then fell in the highest earnings category.

The preference pattern for prime working-age men differed sharply from that for women. At all earnings levels, the proportion of men wanting more hours was substantially larger than the proportion preferring more leisure. In the $300 to $499 earnings range, men preferred more hours 4 to 1 over fewer hours. Even at weekly earnings of $500 and over, only about 8 percent of prime working-age men were willing to trade income for leisure, whereas 15 to 20 percent wanted more hours and more money. Also, the proportion of men satisfied with the length of their workweek continued to rise as earnings increased. The substitution effect seems to outweigh the income effect for prime working-age men—even when earnings are extremely high.

In sum, two of three employed persons in May 1985 said they would prefer to work the number of hours they currently work and earn the same money. An additional one-fourth wanted to work more hours and earn more money. Only 8 percent would choose a shorter workweek and less money. As might be expected, the degree of satisfaction with present hours rose with age and with weekly earnings. In contrast, the proportion wanting to work more hours and earn more money, which was high for young people and low earners, fell sharply as age and earnings increased. Women were more likely than men to prefer fewer hours and a proportionate reduction in pay. Although the proportion of men and women willing to forgo income for leisure time was generally small, it rose steadily as weekly earnings increased. This suggests that at very high earnings, the labor supply curve may bend backward. ☐

[1] See G. Katona, B. Strumpel and E. Zahn, *Aspirations and Affluence* (New York, McGraw-Hill, 1971), pp. 128–33; and Fred Best, "Exchanging Earnings for Leisure: Findings of an Exploratory National Survey on Work Time Preferences" (U.S. Department of Labor, Employment and Training Administration), R&D Monograph 79. The Katona and others questions were asked of a nationally representative sample of household heads. The Harris survey was based on a national sample of employed civilians 17 years of age and over. These two surveys obtained the following results:

	Percent preferring:		
	Same	*Fewer*	*More*
Katona and others, 1966	56	10	34
Louis Harris and Associates, 1978	61	11	28

[2] Leisure in this context represents all time except paid worktime. In other words, it includes time spent on housework, child care, school attendance and numerous other activities that are not commonly defined as leisure.

[3] Economists have argued about the relationship between the wage rate and the quantity of labor supplied since the English mercantilists in the 1600's. The landmark twentieth century work in this field is Lionel Robbins' "On the Elasticity of Demand for Income in Terms of Effort," *Economica*, June 1930, pp. 123–29. After pointing out that the demand for income can also be viewed as the supply of effort, Robbins says there is no *a priori* way to predict how a change in the wage rate will affect hours of work. Rather, one must observe how individuals vary the amount of work done when the wage rate changes. The same point is addressed in terms of income versus substitution effects by Paul A. Samuelson in *Economics*, 3d ed. (New York, McGraw-Hill, 1955), pp. 535–36.

[4] Cross-sectional data on preferences for more and fewer hours of work by weekly earnings are used as proxies for substitution and income effects. Data on hours that individuals chose to work at different pay rates are not available.

[5] Because only one-quarter of the wage and salary workers in the sample are asked the earnings questions, the standard errors of earnings estimates are relatively large. For this reason, percentages are not shown where the base is less than 100,000.

Temporary help workers: who they are, what jobs they hold

These workers are disproportionately female, young, and black; they are more likely to work part time and in clerical and industrial help jobs

WAYNE J. HOWE

Much attention, of late, has been given to the rapid employment growth in the temporary help supply service industry. This industry consists of businesses supplying temporary help to other establishments on a contractual basis.

For the most part, the focus has been on the conditions under which employers prefer to use temporary labor supplied by a temporary help supply agency.[1] For example, an employer with a fluctuating workload, particularly when unpredictable peakloads allow little time to recruit and hire directly, is likely to utilize this service. Also, if a need for additional workers is expected to be short term, a firm might find the costs involved in hiring, particularly those related to recruiting and training, to be excessive. The purchase of temporary help services allows the employer to incur labor costs for only the period the services are required, and to avoid any severence costs. In contrast to the employer-demand focus of earlier analyses, this article provides information about the composition of the temporary help supply service work force and the circumstances under which individuals are attracted to temporary employment.

Data on wage and salary employment in the temporary help supply service industry used in this article are obtained from the May 1985 supplement to the Current Population Survey (CPS), a monthly sample survey of households. This supplement included questions specifically designed to identify workers who viewed their jobs as temporary and whose salaries were being paid by a temporary help supply agency. The characteristics of such workers could then be examined through the information normally collected for all persons in the CPS in terms of their age, sex, race, marital status, full- or part-time employment, and occupation.

It should be noted that the temporary help supply employment industry level derived from the CPS is not strictly comparable to that obtained from the Current Employment Statistics (CES) program. The monthly CES survey derives its estimates from the payroll records of a sample of establishments. In the case of temporary help workers, the CES estimates relate to the total number of jobs in the industry, including those of the personnel who operate the temporary help agencies. By contrast, the new CPS data relate only to those workers who view their jobs as temporary. Thus, these data exclude not only the permanent employees who staff the many agencies, but may also exclude many of the workers who do not view their jobs as temporary, as they have a fairly continuous attachment to the temporary help agency. This explains at least part of the reason the number of temporary help workers identified in the CPS in May 1985—455,000—was much lower than the number of jobs in the temporary help industry as measured through the CES—689,000. The CPS data, while not representative of all the employees in the industry, are representative of the preponderance of them, particularly of those whose jobs are truly temporary. And, the CPS supplies the only information available on the characteristics of these workers.

Wayne J. Howe is an economist in the Division of Employment and Unemployment Analysis, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

Who are these workers?

Just as employer demand for temporary workers increases during times of uncertainty, many workers seek temporary employment due to transitory or uncertain circumstances. Such workers might include teachers and students out of school for the summer or other vacation periods, or persons entering or leaving the labor force gradually. Women and young persons are more likely than others to experience these transitory conditions. Therefore, it should not be surprising that there was a disproportionately high concentration of both groups employed by temporary help supply agencies in May 1985. Almost two-thirds of the industry's work force were women, in contrast to their 2 of 5 proportion of all wage and salary jobs. (See table 1.) This difference clearly reflects the benefits offered to many women by the temporary help supply service industry, particularly the combination of flexible work schedules and the opportunity to acquire needed experience and job market exposure. In addition, the industry has a large number of administrative support jobs, and a disproportionate number of women are traditionally employed in such clerical positions.

Women with family responsibilities are particularly attracted to temporary employment because it provides the flexible work schedules that allow them to reconcile work outside the home with family commitments. Women who reenter the labor force after a long absence may prefer temporary jobs until they are able to find suitable permanent employment. Employment through a temporary help supply agency enables them to test the market by sampling a range of work environments until they find the right employment situation. At the same time, temporary employment allows these workers to acquire needed skills and experience while building confidence and increasing their marketability. Such skills and confidence can be lost during years outside the labor force. Some women prefer the flexibility of the temporary help environment for the long term. In either case, the increasing tendency among firms to contract out for temporary employees, particularly to staff administrative support positions, has provided a growing temporary job market for women.

Table 1. Employed wage and salary workers in all industries and in the temporary help supply industry, by selected characteristics, May 1985

[Percent distribution]

Characteristic	All industries	Temporary help supply industry
Age		
Total, 16 years and over	100.0	100.0
16 to 24	20.1	32.7
25 to 54	67.4	57.6

All other occupations	51.8	48.2

[1] Data not shown where base is less than 75,000.

[2] Includes widowed, divorced, and separated women, not shown separately.

Temporary employment is also appealing to young workers (16–24 years old) who want flexible schedules, allowing time to attend school, or the opportunity to work during vacations. Young workers held 1 of 3 temporary help supply service jobs in May 1985, compared with 1 of 5 wage and salary jobs in all industries. (See table 1.) The representation of young workers in this industry increases during the summer months, when many working mothers leave the labor force to care for school age children and students step in to take their places.[2]

Young persons who have little work experience may also be attracted to employment in temporary help agencies as a means of attaining higher paying permanent positions. Job search costs, in terms of both time and money, can be reduced by allowing a temporary help agency to establish contact with potential employers. However, contracts between employers and temporary help supply agencies may sometimes limit this type of job-switching.

In addition to the large concentration of women and youth, there is also a relatively high proportion of black temporary help workers. About 1 of 5 such workers is black, nearly twice the proportion found among all industries. (See table 1.) Only about half of the black workers in this industry were women, similar to the distribution of the black work force found in all industries. In contrast, among white workers, women accounted for two-thirds of the temporary help work force, but only 44 percent of wage and salary employment in all industries.

While the majority of temporary help supply employees work full time, a very large proportion, 2 of 5, work part time. (See table 2.) This was more than twice the average for all wage and salary workers. Women were less likely than men in this industry to work full time, but this depended largely on their marital status. Almost two-thirds of the single women in temporary help jobs worked full time, while only about half of the married women (with spouse present) did so. As would be expected, young people were less likely to work full time. Only 56 percent of youth age 16 to 24 were employed full time, while 67 percent of the temporary help work force age 25 to 54 were full-time workers.

What jobs do they hold?

Temporary help workers perform a variety of jobs, from service workers earning the minimum wage to highly paid technicians or administrators working as temporary specialists on specific projects. When compared with all industries, however, a particularly large concentration of temporary help workers were in the administrative support and industrial help occupations: indeed, 43 percent held clerical positions such as general office clerks, secretaries, typists, and receptionists—2½ times their proportion in all industries. (See table 1.)

More than 9 of 10 clerical jobs in the temporary help industry were filled by women. Skill requirements for many of these clerical positions are relatively low, but more highly skilled clerical workers, particularly those with word-processing skills, are much in demand; consequently, pay for them is relatively high compared with other clericals. Overall, the demand for temporary workers in clerical positions is less sensitive to seasonal and cyclical changes than is the demand for workers in other occupations. Future job growth is expected to be particularly strong for highly skilled workers who can operate the latest office equipment.[3]

When compared with workers in other occupations within the industry, persons in clerical positions are more likely to work full time—two-thirds of them in May 1985. (See table 2.) Although many clerical workers fill in only for short assignments or for workers who are ill, it is not unusual to work in the same temporary job for weeks or even months. Some stay with the temporary agency until they find permanent employment.

The second largest occupational market in this industry is for industrial help workers—helpers, laborers, handlers, and equipment cleaners. Little work experience is required for many of these jobs, and the demand for these workers is both seasonal and cyclical.[4] Many are employed as fill-ins to handle temporary work overloads or to step in when regular employees are ill or on vacation. Only 55 percent of the workers in these occupations were full time, somewhat lower than the proportion for administrative support workers. Moreover, just as women dominated the administrative support occupation, almost 90 percent of the operators, fabricators, and laborers were men. Finally, there are a large number of low skill, low paying laborer jobs in the temporary help industry, which may be responsible for the high concentration of black workers. Black men in particular are much more likely than their white counterparts to be employed in these jobs.[5]

IN SUMMARY, data from the May 1985 supplement to the CPS show that those temporary workers whose salaries are paid by temporary help firms are disproportionately female, young, and black. They are more likely than workers in other industries to work part time, and they are heavily concentrated in clerical and industrial help occupations. □

Conventions

Steelworkers press organizing and coordinated bargaining

Joy K. Reynolds

The United Steelworkers of America (AFL-CIO, CLC) held its 23rd constitutional convention in Las Vegas, NV, August 25–29, 1986. Some 2,800 delegates took action to implement the two major themes of the convention: celebrating the union's 50th anniversary (the Steel Workers Organizing Committee was formed in June 1936) and addressing future challenges. Delegates enacted constitutional changes that, among other things, broadened the categories of persons eligible for membership and clarified the power to merge small locals. They elected five international tellers to 4-year terms to perform duties in connection with the 1989 referendum election of international officers and passed resolutions dealing with numerous topics, including collective bargaining, plant closings, and employee stock ownership plans. The convention heard speeches from Steelworkers International President Lynn Williams, AFL-CIO President Lane Kirkland, former Steelworkers President I.W. Abel, Amalgamated Clothing and Textile Workers Union President Murray Finley, Canadian Labour Congress (CLC) President Shirley Carr, and numerous national and State or provincial politicians from both the United States and Canada.

Speech highlights

In the keynote address, Steelworkers President Williams, who was reelected to that post in a November 1985 referendum, outlined the results of this year's bargaining in major industries, including containers, aluminum, nonferrous metals, and steel. Williams emphasized that the union intends to maintain its coordinated approach to bargaining despite the breakdown of coordinated strategies on the employer side. He admitted that the steel agreements reached with LTV, Bethlehem, National, and Inland involve sacrifices, but praised the employment security guarantees and profit-sharing aspects of those settlements. He charged that the union's high priority on preserving jobs and limiting contracting out was one major reason that USX (formerly U.S. Steel Corp.) locked out more than 22,000 workers on August 1. Williams thanked the AFL-CIO for its recently formed committee to support the USX workers, about whose efforts Clothing and Textile Workers President Murray Finley later addressed the convention. Williams criticized the trade policies of the U.S. and Canadian governments, arguing that "there is no such thing as free trade"; the union seeks "managed" trade, aimed at raising the standard of living in both seller and buyer nations.

Regarding developments within the Steelworkers "family," Williams cited the union's success in organizing new members, not only in its traditional membership base but also in public sector and other service industry units; the pace of organizing in 1986 was reported to be more than five new units a week. He noted the completion of the merger with the 34,000-member Upholsterers International Union, which became a division of the Steelworkers, with former Upholsterers President John Serembus serving as director.

The continued connection of retirees with the Steelworkers was personified by the appearance at the convention of former union president I.W. Abel, who has been appointed to head SOAR, the Steelworkers Organization of Active Retirees. According to its bylaws, SOAR will "deal with the social, economic, educational, legislative, and political developments and concerns of its members and spouses, the United Steelworkers of America, and the labor movement." President emeritus Abel, whose address anchored that portion of the convention celebrating the Steelworkers' jubilee, reviewed the history of the struggle to organize the steel industry and highlighted accomplishments of the union gained through both collective bargaining and involvement in the legislative process (for example, supporting enactment of the Occupational Safety and Health Act and the Employee Retirement Income Security Act).

In his address to the convention, AFL-CIO President Lane Kirkland pledged the Federation's support to the Steelworkers in its struggle against USX. He urged Government trade and employment policies that would help to preserve the Nation's industrial base, noting that "silicon chips cannot be sold over the counter in a 7-Eleven." He lauded the cooperative efforts of the union in attempting to meet the challenges facing the industry, but warned that such cooperation must be met by reciprocal actions on the part of employers.

Constitutional changes

The convention adopted constitutional changes and policy recommendations in many areas. Among the amendments enacted were the following:

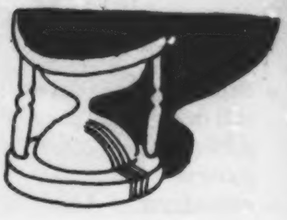
Joy K. Reynolds is an industrial relations specialist at the Bureau of Labor-Management and Cooperative Programs, U.S. Department of Labor.

- Replacement of references to membership in "a plant or mill or any other place" with the words "an enterprise, public or private," to reflect the union's expanding jurisdiction.
- Amendment of Article III to permit membership by supervisors, including those empowered to hire or fire, subject to terms established by the International Executive Board. (Previous language had provided that only supervisors without such powers could join, subject to the specific approval of the local union and the Board). Those opposing this change argued that the union should not rush to embrace persons who are firing their fellow workers. But the amendment carried on a standing vote after members of the constitution committee explained that the language was not intended to apply to mill foremen and supervisors, but is largely aimed at expanding recruitment in the public sector, where, for example, a recently organized unit of middle managers in Boston brought in more than 400 members through the Salaried Employees of North America, a division of the Steelworkers.
- Amendment of Article IV to provide for annual, instead of semiannual, audits of the international union finances.
- Amendment of Article V to provide, in part, that protests regarding local union voting for national officers must be "received' by the international tellers within 15 days of the election. Prior language had required such protests to be "filed" with the tellers no later than 10 days after the election.
- Amendment of Article VII to provide that 100 or more persons (formerly 10) eligible for membership shall constitute a local union upon receipt of a charter from the international secretary. Smaller groups may be chartered upon the authority of the international president. Further, language was added to provide for International Executive Board rules governing transfer of jurisdiction of one local to another. Supporters of these changes cited the large number of small locals (of 4,232 locals, 557 have nine or fewer members and 2,692 have fewer than 100 members) and the strength that comes from amalgamation. They argued that the amendment reflects existing Board power to combine locals and promised that mergers would be accomplished in consultation with district directors and the affected locals. According to Williams, "Obviously those that are functioning properly will continue." Floor discussion was closed before opponents of the measure spoke, as a delegate later took the floor to point out. The outcome of the voice vote being in doubt, a standing vote was held, and the change was adopted.
- Amendment of Article XIV to provide that when the assets of the strike and defense fund exceed $200 million in any month, payments to it shall cease until the balance falls below $150 million, instead of $180 million as previously provided. (Interim payments will be divided equally between the international and local unions.) In response to a resolution that a mechanism be established to enforce local affiliation with State and provincial central bodies, Article XIV was amended to provide for deduction for dues to such bodies from local per capita refunds by the international treasurer with the approval of the international president.
- Addition of Article XVIII to provide an associate membership aimed at organizing new membership and also to provide a means for continued affiliation by laid-off members who have gone beyond the 24-month period provided for continued membership status under Article XI, as well as for persons organized in units that subsequently fail to vote for union representation. The new article provides that associate members shall not be eligible to run or vote for international or local office but may participate in organizations of associates to the extent and under rules provided by the International Executive Board. These members will be eligible for benefits such as prepaid legal services, credit cards, and insurance coverage. Adoption of this category of membership parallels a recommendation of the AFL-CIO's Committee on the Evolution of Work.

Among the constitutional amendments proposed but not adopted were those reducing or capping members' dues and salaries of international officers and district directors, providing full voting membership for retirees, providing mail ballots in elections of international officers, expanding the access of members to absentee ballots in such elections, permitting locals to hold quarterly rather than monthly meetings, and providing for removal of local officers without "costly" trial procedures. In the collective bargaining area, amendments considered but not adopted included those to postpone conventions in years of major contract negotiations, to hold conventions in cities most affected by layoffs of members, to increase the amount of strike benefits, and to provide for strike benefits payment as a matter of right rather than after determination of need by the local union.

Other actions

As the union's "court of last resort," the convention heard appeals on matters such as local elections and trial procedures. The convention also adopted resolutions in the areas of politics, collective bargaining strategies and specific disputes, and legislative policies. For example, the union endorsed new strategies in collective bargaining, including consumer boycotts and corporate campaigns; adopted standards for the negotiation of Employee Stock Ownership Plans (they must be part of the labor agreement, must never be used as a substitute for an adequate, funded, Government-guaranteed pension plan, and should be based on thorough analysis of the company's finances and prospects for survival); and endorsed legislation to require advance notice of plant closings and bargaining over alternatives to closings or layoffs. □



Major Agreements Expiring Next Month

This list of selected collective bargaining agreements expiring in December is based on information collected by the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more. Private industry is arranged in order of Standard Industrial Classification.

Industry or activity	Employer and location	Labor organization[1]	Number of workers
Private			
Construction	Constructors Association of Western Pennsylvania (Pennsylvania)	Operating Engineers	3,000
	Constructors Association of Western Pennsylvania (Pennsylvania)	Laborers	3,600
	National Electrical Contractors Association, Western Pennsylvania Chapter (Pennsylvania)	Electrical Workers (IBEW)	1,500
Food products	Iowa Beef Processors, Inc. (Nebraska)	Food and Commercial Workers	2,000
Apparel	Plastic Soft Material Manufacturers Association (New York, NY)	Ladies' Garment Workers	2,600
Paper	Westvaco Corp. (Virginia and Maryland)	Paperworkers	1,050
Primary metals	Huntington Alloys Inc. (Huntington WV)	Steelworkers	1,000
	Copperweld Corp. (Warren, OH)	Steelworkers	2,000
	Neenah Foundry Co. (Neenah, WI)	Molders	1,000
Electrical products	AVX Corp., AVX Ceramics (Myrtle Beach, SC)	Electrical Workers (IBEW)	1,400
Transportation equipment	Dana Corp. (Interstate)	Auto Workers	7,000
Water transportation	Great Lakes Association of Stevedores (Interstate)	Longshoremen's Association	6,000
Air transportation	Northwest Airlines, flight attendants (Interstate)	Teamsters (Ind.)	3,000
	Republic Airlines, clerical and office (Interstate)	Air Line Pilots	6,300
	Western Airlines, pilots (Interstate)	Air Line Pilots	1,200
	Ozark Airlines, clerical and office (Interstate)	Machinists	1,800
Communication	General Telephone Co. of Pennsylvania (Pennsylvania)	Electrical Workers (IBEW)	2,000
Utilities	Public Service Co. of Colorado (Denver, CO)	Electrical Workers (IBEW)	3,000
	Southern California Edison Co. (California)	Electrical Workers (IBEW)	5,750
Wholesale trade	New York Oil Heating Association (New York, NY)	Teamsters (Ind.)	1,700
Retail trade	New York-Bronx Meat and Food Dealers Inc. (New York, NY)	Food and Commercial Workers	1,600
	Kroger Co. (Dayton, OH)	Food and Commercial Workers	2,000
Restaurants	San Mateo Hotel and Restaurant Owners Association (California)	Hotel Employees and Restaurant Employees	5,200
	Bob's Big Boy Restaurants (California)	Bob's Employees' Association (Ind.)	5,200
Real estate	Realty Advisory Board on Labor Relations, Inc., Commercial Building Agreement (New York, NY)	Service Employees	18,000
Services	Service Employers Association (New York)	Service Employees	36,000
	Associated Guard and Patrol Agencies (Chicago, IL)	Service Employees	6,000
Public			
General government	Alaska: State general unit	State Employees Association	7,900
	State labor trades and crafts	Laborers	1,500
	Minnesota: Hennepin County general unit	State, County and Municipal Employees	3,000
	Florida: Dade County classified employees	State, County and Municipal Employees	10,000
	New York: Broome County white-collar employees	Civil Service Employees Association	1,100
	Dutchess County general unit	State, County and Municipal Employees	1,200
	Oneida County general unit	Civil Service Employees Association	1,000
	Onondaga County general unit	State, County and Municipal Employees	3,500
	Orange County general unit	State, County and Municipal Employees	1,500
	Chautauqua County general unit	Civil Service Employees Association	1,200
	Nebraska: Omaha municipal employees	State, County and Municipal Employees	1,050
	Wisconsin: Milwaukee County general unit	State, County and Municipal Employees	6,000
	Milwaukee municipal employees	State, County and Municipal Employees	2,800
Law enforcement	Milwaukee Police Department	Police Association	1,800
	Ohio: Cincinnati Police Department	Police	1,050
Fire protection	Pennsylvania: Pittsburgh Fire Department	Fire Fighters	1,050
Education	California: San Diego Unified School District, office	Education Association (Ind.)	2,300
	Colorado: Boulder District 21, teachers	Education Association (Ind.)	1,250
	Cherry Creek teachers	Education Association (Ind.)	1,500

Developments in Industrial Relations

Steel update

The financially beleagured steel industry continued to suffer, as USX Corp. and Timken Co. were involved in work stoppages; Armco Inc. was unable to negotiate cuts in labor costs it had sought at its Middletown, OH, mill; and LTV Corp. filed for bankruptcy.

The Armco settlement with the Armco Employees Independent Federation does provide for a wage and benefit freeze for the 42-month contract term, but the company had been seeking a paycut of more than 75 cents an hour, cuts in holiday, vacation, and insurance benefits, and adoption of a two-tier pay system.

Armco said it accepted the terms, which ended a 5-day strike by the 4,200 employees, "primarily in the interest of the customer and [out of] growing concern for the company's financial position." Armco's ability to sustain a long strike was hampered by its financial commitments, including an $85 million pension payment due September 13.

Despite the company's dissatisfaction with the overall settlement, it did win the right to reopen negotiations in March of 1988 and 1989 if the mill fails to earn $50 million before taxes on operations during the preceding calendar year. However, the union maintains that even if earnings are below $50 million, the provision could be exercised only with its consent.

At USX Corp., there was a continuing dispute over which side impelled the stoppage that began on August 1, when the previous contract expired. The United Steelworkers contended the stoppage was a lockout, which would enable the idled employees to draw State unemployment benefits. According to USX, the stoppage was a strike, precluding the employees from drawing unemployment benefits. There was no single answer from the affected States—Pennsylvania, Ohio, Alabama, and Minnesota ruled the stoppage a lockout, while Illinois and Utah held that it was a strike. In some cases, the rulings were being appealed.

Both the company and the United Steelworkers viewed the Timken Co. stoppage as a strike. The 5,800 employees walked out of the three Ohio plants after the company demanded a 60-cent-an-hour wage decrease, and the union countered by offering a wage and benefit freeze.

The most significant recent event in the steel industry was LTV Corp., filing for protection from creditors under Chapter 11 of the bankruptcy code. LTV is the Nation's second largest steel producer. At the time, LTV reported assets of $6.14 billion and liabilities of $4.59 billion. The attempt to reorganize and return to profitability came just 3 months after the United Steelworkers had agreed to a $3.15 an hour cut in wages and benefits to aid the company, which has suffered $1.7 billion in losses since 1982. (See *Monthly Labor Review*, June 1986, p. 45.) The bankruptcy filing meant that further compensation cuts might be required of the employees, particularly after LTV officially informed the union that it wanted to renegotiate the April contract. The union's initial response was that it would not automatically agree to the proposal. The filing also raises the possibility that other companies that had already settled would press for renegotiation of their contracts to maintain competitive parity with LTV.

In conjunction with the Chapter 11 filing, LTV cancelled health and life insurance benefits for 76,000 retirees, including 61,000 retired Steelworkers. This triggered a strike by 4,400 workers at LTV's Indiana Harbor Works in East Chicago, IN, as well legal action by the Steelworkers to force a restoration of the benefits. The strike ended after 5 days when a bankruptcy judge acceded to LTV's request for permission to restore the benefits. The company said that ending the walkout was vital to improving its financial condition.

In another indication of LTV's difficult financial condition, the company asked the Pension Benefit Guaranty Board (PBGB) to assume payments to retirees covered by one pension plan, and the PBGB itself moved to take control of another underfunded plan. These events, combined with a possible PBGB takeover of two other LTV pension plans, could raise the PBGB obligation to more than $2.5 billion.

Dispute settled in meat processing

In the meat processing industry, a long dispute that pitted employees against management and a local union against the parent United Food and Commercial Workers (UFCW) apparently ended when the UFCW settled with Geo. A Hormel and Co.'s flagship plant in Austin, MN. Concurrent with the Austin accord, Hormel and the UFCW also negotiated a new contract for seven plants in six states. The difficulties at the Austin plant, which included a "corporate

---

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

campaign" against Hormel that was initiated by the Local P-9 before the UFCW removed its officers and a year-long strike that ended with the contract settlement, can be traced through a number of developments in recent years:

- In 1982, Local P-9 agreed to a 3-year contract that included a no-strike guarantee, as well as elimination of an incentive pay plan. In return for these inducements to locate a new $100 million plant in Austin, Hormel pledged to maintain the employees standard wage rate at the same level as at other major companies in the industry.
- In 1983, the industry was hit by bankruptcies and plant closings, leading to cuts in the previous $10.69 an hour standard pay rate. Hormel pressed employees at all eight of its plants for similar cuts to remain competitive. Unlike employees at the other plants, those in Austin rejected the offer, contending that the "me-too" clause in their contract was only intended to raise wages. An arbitrator later ruled that Hormel could cut the rate at Austin to between $8 and $9 an hour.
- In 1984, employees of the seven other plants negotiated with Hormel on the issue and settled on an immediate $9 rate, rising to $10 in September 1985. Austin employees rejected the proposal and initiated the corporate campaign to bring consumer pressure against Hormel. At the same time, Hormel cut the pay rate to $8.25 at Austin. Leaders of the parent union condemned Local P-9's action in breaking ranks with the other locals and questioned the value of the corporate campaign tactic. Despite the condemnation, the local did not change.
- In August 1985, 1,400 employees struck the plant after negotiators failed to agree on a new contract to succeed the 1982 contract. To increase pressure on the company, Local P-9 accelerated the corporate campaign, which was declared to be an illegal secondary boycott in a National Labor Relations Board ruling issued the following month.
- In January 1986, Hormel began hiring replacements for the strikers, leading to intensified picketing at the plant and a call-up of the National Guard, as well as efforts by pickets to increase pressure on Hormel by traveling to other company plants. This led to the firing of 500 workers at the Ottumwa, IA, plant for honoring the roving picket line. At the end of the month, Hormel said that it had nearly a full work force, comprising 550 returning strikers and 550 replacement workers.
- In March 1986, the UFCW declared the strike a lost cause and moved to place Local P-9 in trusteeship, leading to legal actions that culminated in a ruling that the UFCW's action was proper.
- In July 1986, some of the former strikers formed the North American Meatpackers Union in an attempt to eventually supplant the UFCW as bargaining agent for the Austin employees.
- In August 1986, Hormel and the UFCW settled for the Austin operations. The accord provides for pay increases totaling 70 cents an hour for the strikers who returned to work in January. The replacement workers hired in January also will move up to $10.70 an hour over the contract term. Previously, they were paid $8 an hour to start and a maximum of $9 later. The union did not win immediate rehiring of the strikers who remained out until the stoppage was concluded, but Hormel did agree that for 2 years the strikers will have priority in filling openings that occur.

The new Austin contract runs for 4 years, compared with 3 years for the other locations, where concurrent settlements resulted in the same pay rates as for Austin. Hormel said that in the 1990 negotiations for the seven plants, it will agree to a common expiration date at all locations, including Austin, a major union goal to strengthen its bargaining position. The seven plants are in Fremont, NE, Beloit, WI, Algona, IA, Charlotte, NC, Dallas and Houston, TX, and Atlanta, GA.

In a related event, an arbitrator ordered Hormel to rehire the 500 workers it had fired in January for refusing to cross picket lines. Hormel accepted the ruling in principle, but noted that the January shutdown of part of the Ottumwa facility precluded rehiring all of the workers.

Elsewhere in meat processing, the UFCW settled with Oscar Mayer Co. for 2,300 workers in Davenport, IA, Madison, WI, and Chicago, IL. The 3-year accord provides for wage increases totaling 65 cents an hour, bringing the standard rate to $10.70; a new supplemental retirement plan; an additional paid holiday; and health care improvements.

Chrysler farms out work to American Motors

In an unusual move, Chrysler Corp. contracted out production of its large, rear-drive cars to American Motors Corp. (AMC). Chrysler said the farm-out was necessitated by the planned conversion of its St. Louis plant from large car to van production and by the unexpected continuing high demand for the large cars.

A major factor in winning the production contract was an agreement between AMC and Local 72 of the Auto Workers that lowered labor costs at the company's Kenosha, WI, plant, where the Chrysler cars will be produced on an assembly line that had been idle because of slow sales of AMC cars. The plant's other assembly line will continue to assemble AMC cars.

The AMC-Local 72 accord cut the 162 job classifications to 14 for skilled trade workers and to 32 for other workers. The number of classifications was a difficult issue, but a settlement did not come until the bargainers agreed on the precise duties each classification will encompass.

Locals of the Machinists and Teamsters unions also aided in the winning of the production contract by agreeing to cost-cutting measures for about 400 employees in Kenosha. UAW Local 75 also agreed to a cut in job classifications and other contract changes at AMC's parts plants in Milwaukee.

According to Chrysler, the production contract was expected to run for $2^1/_2$ years, with an option for extension. Despite the pickup in production, which was expected to result in the recall of more than 3,000 laid-off AMC employees, the company continued to indicate that it considered the Kenosha facility to be obsolete and that it was considering the possibility of opening a replacement plant in Kenosha, or elsewhere in the United States.

Talks completed for 'Chrysler Electronics City'

Another step toward the expected 1988 opening of "Chrysler Electronics City" in Huntsville, AL, occurred when the company and Auto Workers Local 1413 agreed on a contract to become effective in 1988. The favorable vote by the local union's members, who are employed at other Chrysler facilities in the area, was 706 to 256. A union official said the contract will provide for "substantial" wage increases, a reduction in job classifications, and "pay-for-knowledge" provisions under which employees will receive higher pay for mastering more than one job.

The plant, covering 750,000 square feet on a 325 acre site, will produce electronic components for Chrysler vehicles. Chrysler hopes to attract some of its suppliers to the site. The plant is expected to employ 2,500 UAW members.

GM offers departure incentives

General Motors Corp. moved to reduce operating costs by announcing "incentives" to resign or retire that could be offered to any white-collar employee of the company's North American automotive operations. This was part of the company's announced plan to reduce its white-collar work force by 25 percent by 1989. GM currently has 133,000 salaried employees involved in automotive production in the United States and 9,000 in Canada.

The announcement was applauded by industry observers who contended that GM is overstaffed, compared with Ford Motor Co. and Chrysler Corp., which have been reducing their white-collar staffs since the early 1980's. GM did offer departure inducements to white-collar workers in 1984, and an undisclosed number accepted. Under the 1986 program, the inducements were to be made to individuals at the discretion of management. The affected employees could refuse the offer.

Police officers pick assignments, work schedules

The Arlington County, VA., police department has adopted an experimental program under which officers demonstrating superior performance will have priority in picking their beats and days they work. Previously, assignments and work schedules were based strictly on length of service. A department official said the program was established because "there are always people who work harder than other people, and we had no way to reward them." The experiment is limited to the 29-member day section.

Under the evaluation procedure of the new program, officers will receive 1 point for issuing a parking ticket, ranging up to 50 points for a felony arrest. If the program proves workable during the 6-month trial, officers who average at least 35 points a day during the period will be given priority in selecting neighborhood assignments and work schedules for the next 12 months. Within the group of eligible officers, those with the most seniority would have the first choice.

The president of the Arlington County Police Beneficial Association said it was too early to comment on the experiment. Under Virginia law, public employee unions can discuss contract provisions with employers, but they are not permitted to engage in binding collective bargaining.

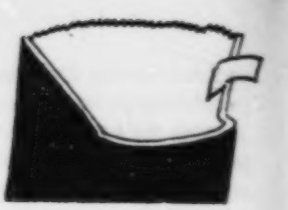
Shipbuilding companies bargain separately

Bargaining in the West Coast shipbuilding industry led off with a settlement between Todd Shipyard Corp.'s Los Angeles shipyard and Local 9 of the Marine and Shipbuilding Workers. The 3-year accord could set a pattern for settlements between other shipyards and the Pacific Coast Metal Trades Council, comprising 11 unions with 10,000 members. Since the 1950's, the employers had bargained with the Trades Council as a unit, the Pacific Coast Shipbuilders Association, but the member companies decided to bargain individually in 1986.

The 3-year Todd agreement froze top pay rates, leaving most workers at the $13.48 an hour rate that applies to nearly all trades. There was a change in pay progression, with new employees starting at $9.50 an hour and moving to the top rate after 3 years. Previously, they started at $8.50.

Todd also agreed to take over a union-administered pension and benefit plan, to establish a health maintenance organization, to offer dental coverage, and to increase sickness and accident benefits. □

Book Reviews



Labor in a turbulent era

American Workers, American Unions, 1920–1985. By Robert H. Zieger. Baltimore, MD, The Johns Hopkins University Press, 1986. 233 pp. $25, cloth; $9.95, paper.

Books on the history of the American workers and their unions are a rare occurrence indeed and for this reason alone Professor Robert H. Zieger's contribution is to be welcomed. Within the scope he has set for himself—no new sources and no original research—Zieger has succeeded in delineating the major economic and political events that have shaped the current labor movement and that in turn have been shaped by it. Although the author's sympathies are clear throughout the volume, the treatment of issues is even-handed, an approach further supported by a judiciously selected bibliography. It should serve as an excellent supplementary text in undergraduate courses in industrial relations and labor economics.

In his first chapter, the author takes us, perhaps too quickly, through the 1920's, stressing the economic plight of millions of workers during these much acclaimed years of prosperity.

Organized labor's massive and unexpected gains during the 1930's are the subject of chapter 2, which includes an insightful treatment of John L. Lewis, the CIO, and the organizing campaigns in steel, auto, and other manufacturing industries.

Chapter 3 discusses labor's role during World War II, a subject typically ignored in general history texts or those devoted to that period. Students of the labor movement will be grateful to the author not only for his discussion of black and women workers, but also for drawing attention to the flip-flop of the Communist party and its adherents before and after the German-Russian nonaggression pact. Unfortunately, his criticism of the National War Labor Board leads him to overlook the fact that the Board's policies, while trying to maintain some degree of wage control, also set the stage for an unprecendented growth in fringe benefits.

An undue emphasis on political radicalism and its effects on organized labor mars chapter 4. While the candidacy of Henry A. Wallace did garner some support from a few unions and while Jay Lovestone was indeed an interesting figure in the top echelon of the AFL, the extended discussion given to these matters is likely to leave the general reader with the impression that all of this was of major concern to workers and their unions. Even more regrettable are several characterizations such as ". . . the ouster of the Communist-oriented elements in 1949-50 and the attacks on the expelled affiliates . . . usually degenerated into repression and violence." It needs to be remembered that, for example, the contest between the International Union of Electrical, Radio and Machine Workers (IUE) and the United Electrical, Radio and Machine Workers of America (UE) was decided in representation elections conducted by the National Labor Relations Board, and not by strong-arm tactics.

Chapter 5 describes the merger between the AFL-CIO in 1955 and the surprising gains scored by unions among workers in the public sector. Chapter 6 takes us into the 1960's and closes with the defeat of Hubert Humphrey in 1968, described as labor's political "Last Hurrah," an event it can be argued that actually occurred as early as 1947.

In what appears to be an attempt to give the book greater currency, the author added a 7-page epilogue, "Into the Eighties." This, unfortunately, was a mistake since many issues facing labor are either barely referred to or are omitted altogether. It is hoped that the author will do full justice to these topics in the next edition.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force, employment, unemployment, collective bargaining settlements, consumer, producer, and international prices, productivity, international comparisons, and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described, key definitions are given, notes on the data are set forth, and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. (Seasonally adjusted data appear in tables 1–3, 4–10, 13, 14, 17, and 18.) Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are seasonally adjusted with a procedure called X–11 ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method previously used by BLS. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada, Catalogue No. 12–564E, February 1980). The second change is that seasonal factors are calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at midyear for the July-December period. However, revisions of historical data continue to be made only at the end of each calendar year.

Seasonally adjusted labor force data in tables 1 and 4–10 were revised in the February 1986 issue of the *Review*, to reflect experience through 1985.

Annual revisions of the seasonally adjusted payroll data shown in tables 13, 14, and 18 were made in the July 1986 *Review* using the X-11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in table 42 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the Hourly Earnings Index in table 17—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The $2 (or any other resulting values) are described as "real," "constant," or "1967" dollars.

Additional information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule preceding these general notes. More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in *Employment and Earnings*, a monthly publication of the Bureau. More data from the household survey are published in the two-volume data book—*Labor Force Statistics Derived From the Current Population Survey*, Bulletin 2096. More data from the establishment survey appear in two data books—*Employment, Hours, and Earnings, United States*, and *Employment, Hours, and Earnings, States and Areas*, and the annual supplements to these data books. More detailed information on employee compensation and collective bargaining settlements is published in the monthly periodical, *Current Wage Developments*. More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report*, and *Producer Prices and Price Indexes*. Detailed data on all of the series in this section are provided in the *Handbook of Labor Statistics*, which is published biennally by the Bureau. BLS bulletins are issued covering productivity, injury and illness, and other data in this section. Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.
n.e.s. = not elsewhere specified.

COMPARATIVE INDICATORS
(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-to-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonagricultural payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in: consumer prices for all urban consumers; producer prices by stage of processing; and the overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data. For detailed descriptions of each data series, see *BLS Handbook of Methods*, Volumes I and II, Bulletins 2134–1 and 2134–2 (Bureau of Labor Statistics, 1982 and 1984, respectively), as well as the additional bulletins, articles, and other publications noted in the separate sections of the *Review*'s "Current Labor Statistics Notes." Historical data for many series are provided in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). Users may also wish to consult *Major Programs, Bureau of Labor Statistics*, Report 718 (Bureau of Labor Statistics, 1985).

EMPLOYMENT DATA

(Tables 1; 4–21)

Household survey data

Description of the series

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 59,500 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all civilians who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. Members of the Armed Forces stationed in the United States are also included in the employed total. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **overall unemployment rate** represents the number unemployed as a percent of the labor force, including the resident Armed Forces. The **civilian unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **labor force** consists of all employed or unemployed civilians plus members of the Armed Forces stationed in the United States. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons who are retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy, and members of the Armed Forces stationed in the United States. The **labor force participation rate** is the proportion of the noninstitutional population that is in the labor force. The **employment-population ratio** is total employment (including the resident Armed Forces) as a percent of the noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 4–10 are seasonally adjusted, based on the seasonal experience through December 1985.

Additional sources of information

For detailed explanations of the data, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 1, and for additional data, *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). A detailed description of the Current Population Survey as well as additional data are available in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*. Historical data from 1948 to 1981 are available in *Labor Force Statistics Derived from the Current Population Survey: A Databook*, Vols. I and II, Bulletin 2096 (Bureau of Labor Statistics, 1982).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Establishment survey data

Description of the series

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by more than 250,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include working supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12–17 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in the following industries: transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and

services. These groups account for about four-fifths of the total employment on private nonagricutural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index, introduced in the May 1983 *Review*, represents the percent of 185 nonagricultural industries in which employment was rising over the indicated period. One-half of the industries with unchanged employment are counted as rising. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. The diffusion index is useful for measuring the dispersion of economic gains or losses and is also an economic indicator.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1986 data, published in the July 1986 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Unadjusted data have been revised back to April 1984; seasonally adjusted data have been revised back to January 1981. These revisions were published in the *Supplement to Employment and Earnings* (Bureau of Labor Statistics, 1986). Unadjusted data from April 1985 forward, and seasonally adjusted data from January 1982 forward are subject to revision in future benchmarks.

In the establishment survey, estimates for the 2 most recent months are based on incomplete returns and are published as preliminary in the tables (13 to 16 in the *Review*). When all returns have been received, the estimates are revised and published as final in the third month of their appearance. Thus, August data are published as preliminary in October and November and as final in December. For the same reason, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Thus, second-quarter data are published as preliminary in August and September and as final in October.

Additional sources of information

Detailed data from the establishment survey are published monthly in the BLS periodical, *Employment and Earnings*. Earlier comparable unadjusted and seasonally adjusted data are published in *Employment, Hours, and Earnings, United States, 1909–84*, Bulletin 1312–12 (Bureau of Labor Statistics, 1985) and its annual supplement. For a detailed discussion of the methodology of the survey, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 2. For additional data, see *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Unemployment data by State

Description of the series

Data presented in this section are obtained from two major sources—the Current Population Survey (CPS) and the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act and the Public Works and Economic Development Act. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for 11 States—California, Florida, Illinois, Massachusetts, Michigan, New York, New Jersey, North Carolina, Ohio, Pennsylvania, and Texas—are obtained directly from the CPS, because the size of the sample is large enough to meet BLS standards of reliability. Data for the remaining 39 States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates for the 11 States are revised to new population controls. For the remaining States and the District of Columbia, data are benchmarked to annual average CPS levels.

Additional sources of information

Information on the concepts, definitions, and technical procedures used to develop labor force data for States and sub-State areas as well as additional data on sub-States are provided in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*, and the annual report, *Geographic Profile of Employment and Unemployment* (Bureau of Labor Statistics). See also *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 4.

COMPENSATION AND WAGE DATA

(Tables 1–3; 22–29)

COMPENSATION AND WAGE DATA are gathered by the Bureau from business establishments, State and local governments, labor unions, collective bargaining agreements on file with the Bureau, and secondary sources.

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It uses a fixed market basket of labor—similar in concept to the Consumer Price Index's fixed market basket of goods and services—to measure change over time in employer costs of employing labor. The index is not seasonally adjusted.

Statistical series on total compensation costs and on wages and salaries are available for private nonfarm workers excluding proprietors, the self-employed, and household workers. Both series are also available for State and local government workers and for the civilian nonfarm economy, which consists of private industry and State and local government workers combined. Federal workers are excluded.

The Employment Cost Index probability sample consists of about 2,200 private nonfarm establishments providing about 12,000 occupational observations and 700 State and local government establishments providing

3,500 occupational observations selected to represent total employment in each sector. On average, each reporting unit provides wage and compensation information on five well-specified occupations. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Beginning with June 1986 data, fixed employment weights from the 1980 Census of Population are used each quarter to calculate the indexes for civilian, private, and State and local governments. (Prior to June 1986, the employment weights are from the 1970 Census of Population.) These fixed weights, also used to derive all of the industry and occupation series indexes, ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the bargaining status, region, and metropolitan/nonmetropolitan area series, however, employment data by industry and occupation are not available from the census. Instead, the 1980 employment weights are reallocated within these series each quarter based on the current sample. Therefore, these indexes are not strictly comparable to those for the aggregate, industry, and occupation series.

Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980 to produce, when combined with the wages and salaries series, a measure of the percent change in employer costs for employee total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the *civilian* nonfarm economy (excluding Federal employees). Historical indexes (June 1981 = 100) of the quarterly rates of change are presented in the May issue of the BLS monthly periodical, *Current Wage Developments*.

Additional sources of information

For a more detailed discussion of the Employment Cost Index, see the *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 11, and the following *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor'," July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; "Estimation procedures for the Employment Cost Index," May 1982; and "Introducing new weights for the Employment Cost Index," June 1985.

Data on the ECI are also available in BLS quarterly press releases issued in the month following the reference months of March, June, September, and December; and from the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Collective bargaining settlements

Description of the series

Collective bargaining settlements data provide statistical measures of negotiated adjustments (increases, decreases, and freezes) in compensation (wage and benefit costs) and wages alone, quarterly for private industry and semiannually for State and local government. Compensation measures cover all collective bargaining situations involving 5,000 workers or more and wage measures cover all situations involving 1,000 workers or more. These data, covering private nonagricultural industries and State and local governments, are calculated using information obtained from bargaining agreements on file with the Bureau, parties to the agreements, and secondary sources, such as newspaper accounts. The data are not seasonally adjusted.

Settlement data are measured in terms of future specified adjustments: those that will occur within 12 months after contract ratification—first-year—and all adjustments that will occur over the life of the contract expressed as an average annual rate. Adjustments are worker weighted. Both first-year and over-the-life measures exclude wage changes that may occur under cost-of-living clauses that are triggered by future movements in the Consumer Price Index.

Effective wage adjustments measure all adjustments occurring in the reference period, regardless of the settlement date. Included are changes from settlements reached during the period, changes deferred from contracts negotiated in earlier periods, and changes under cost-of-living adjustment clauses. Each wage change is worker weighted. The changes are prorated over all workers under agreements during the reference period yielding the average adjustment.

Definitions

Wage rate changes are calculated by dividing newly negotiated wages by the average hourly earnings, excluding overtime, at the time the agreement is reached. Compensation changes are calculated by dividing the change in the value of the newly negotiated wage and benefit package by existing average hourly compensation, which includes the cost of previously negotiated benefits, legally required social insurance programs, and average hourly earnings.

Compensation changes are calculated by placing a value on the benefit portion of the settlements at the time they are reached. The cost estimates are based on the assumption that conditions existing at the time of settlement (for example, methods of financing pensions or composition of labor force) will remain constant. The data, therefore, are measures of negotiated changes and not of total changes in employer cost.

Contract duration runs from the effective date of the agreement to the expiration date or first wage reopening date, if applicable. Average annual percent changes over the contract term take account of the compounding of successive changes.

Notes on the data

Care should be exercised in comparing the size and nature of the settlements in State and local government with those in the private sector because of differences in bargaining practices and settlement characteristics. A principal difference is the incidence of cost-of-living adjustment (COLA) clauses which cover only about 2 percent of workers under a few local government settlements, but cover 50 percent of workers under private sector settlements. Agreements without COLA's tend to provide larger specified wage increases than those with COLA's. Another difference is that State and local government bargaining frequently excludes pension benefits which are often prescribed by law. In the private sector, in contrast, pensions are typically a bargaining issue.

Additional sources of information

For a more detailed discussion on the series, see the BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 10. Comprehensive data are published in press releases issued quarterly (in January, April, July, and October) for private industry, and semi-

annually (in February and August) for State and local government. Historical data and additional detailed tabulations for the prior calendar year appear in the April issue of the BLS monthly periodical, *Current Wage Developments*.

Work stoppages

Description of the series

Data on **work stoppages** measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of time lost because of stoppage.

Data are largely from newspaper accounts and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

Additional sources of information

Data for each calendar year are reported in a BLS press release issued in the first quarter of the following year. Monthly data appear in the BLS monthly periodical, *Current Wage Developments*. Historical data appear in the *BLS Handbook of Labor Statistics*.

Other compensation data

Other BLS data on pay and benefits, not included in the Current Labor Statistics section of the *Monthly Labor Review*, appear in and consist of the following:

Industry Wage Surveys provide data for specific occupations selected to represent an industry's wage structure and the types of activities performed by its workers. The Bureau collects information on weekly work schedules, shift operations and pay differentials, paid holiday and vacation practices, and information on incidence of health, insurance, and retirement plans. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Monthly Labor Review*.

Area Wage Surveys annually provide data for selected office, clerical, professional, technical, maintenance, toolroom, powerplant, material movement, and custodial occupations common to a wide variety of industries in the areas (labor markets) surveyed. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Review*.

The National Survey of Professional, Administrative, Technical, and Clerical Pay provides detailed information annually on salary levels and distributions for the types of jobs mentioned in the survey's title in private employment. Although the definitions of the jobs surveyed reflect the duties and responsibilities in private industry, they are designed to match specific pay grades of Federal white-collar employees under the General Schedule pay system. Accordingly, this survey provides the legally required information for comparing the pay of salaried employees in the Federal civil service with pay in private industry. (See Federal Pay Comparability Act of 1970, 5 U.S.C. 5305.) Data are published in a BLS news release issued in the summer and in a bulletin each fall; summaries and analytical articles also appear in the *Review*.

Employee Benefits Survey provides nationwide information on the incidence and characteristics of employee benefit plans in medium and large establishments in the United States, excluding Alaska and Hawaii. Data are published in an annual BLS news release and bulletin, as well as in special articles appearing in the *Review*.

PRICE DATA
(Tables 2; 30–41)

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all urban consumer index (CPI-U) introduced in 1978 is representative of the 1972–73 buying habits of about 80 percent of the noninstitutional population of the United States at that time, compared with 40 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 24,000 retail establishments and 24,000 tenants in 85 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 28 major urban centers are presented in table 31. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI-U. A rental equivalence method replaced the

asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes.

Additional sources of information

For a discussion of the general method for computing the CPI, see *BLS Handbook of Methods, Volume II, The Consumer Price Index*, Bulletin 2134–2 (Bureau of Labor Statistics, 1984). The recent change in the measurement of homeownership costs is discussed in Robert Gillingham and Walter Lane, "Changing the treatment of shelter costs for homeowners in the CPI," *Monthly Labor Review*, June 1982, pp. 9–14.

Additional detailed CPI data and regular analyses of consumer price changes are provided in the *CPI Detailed Report*, a monthly publication of the Bureau. Historical data for the overall CPI and for selected groupings may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Producer Price Indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 60,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The stage of processing structure of Producer Price Indexes organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1976, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

Notes on the data

Beginning with the January 1986 issue, the *Review* is no longer presenting tables of Producer Price Indexes for commodity groupings, special composite groups, or SIC industries. However, these data will continue to be presented in the Bureau's monthly publication *Producer Price Indexes*.

The Bureau has completed the first major stage of its comprehensive overhaul of the theory, methods, and procedures used to construct the Producer Price Indexes. Changes include the replacement of judgment sampling with probability sampling techniques; expansion to systematic coverage of the net output of virtually all industries in the mining and manufacturing sectors; a shift from a commodity to an industry orientation; the exclusion of imports from, and the inclusion of exports in, the survey universe; and the respecification of commodities priced to conform to Bureau of the Census definitions. These and other changes have been phased in gradually since 1978. The result is a system of indexes that is easier to use in conjunction with data on wages, productivity, and employment and other series that are organized in terms of the Standard Industrial Classification and the Census product class designations.

Additional sources of information

For a discussion of the methodology for computing Producer Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 7.

Additional detailed data and analyses of price changes are provided monthly in *Producer Price Indexes*. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

International price indexes

Description of the series

The BLS **International Price Program** produces quarterly export and import price indexes for nonmilitary goods traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts: it includes corporations, businesses, and individuals but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents. With publication of an all-import index in February 1983 and an all-export index in February 1984, all U.S. merchandise imports and exports now are represented in these indexes. The reference period for the indexes is 1977 = 100, unless otherwise indicated.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected quarterly by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first 2 weeks of the third month of each calendar quarter—March, June, September, and December. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined by the 4- and 5-digit level of detail of the Standard Industrial Trade Classification System (SITC). The calculation of indexes by SITC category facilitates the comparison of U.S. price trends and sector production with similar data for other countries. Detailed indexes are also computed and published on a Standard Industrial Classification (SIC-based) basis, as well as by end-use class.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. Price relatives are assigned equal importance within each weight category and are then aggregated to the SITC level. The values assigned to each weight category are based on trade value figures compiled

by the Bureau of the Census. The trade weights currently used to compute both indexes relate to 1980.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's quarterly questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

For the export price indexes, the preferred pricing basis is f.a.s. (free alongside ship) U.S. port of exportation. When firms report export prices f.o.b. (free on board), production point information is collected which enables the Bureau to calculate a shipment cost to the port of exportation. An attempt is made to collect two prices for imports. The first is the import price f.o.b. at the foreign port of exportation, which is consistent with the basis for valuation of imports in the national accounts. The second is the import price c.i.f. (cost, insurance, and freight) at the U.S. port of importation, which also includes the other costs associated with bringing the product to the U.S. border. It does not, however, include duty charges.

Additional sources of information

For a discussion of the general method of computing International Price Indexes, see BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 8.

Additional detailed data and analyses of international price developments are presented in the Bureau's quarterly publication *U.S. Import and Export Price Indexes* and in occasional *Monthly Labor Review* articles prepared by BLS analysts. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

PRODUCTIVITY DATA

(Tables 2; 42—44)

U. S. productivity and related data

Description of the series

The productivity measures relate real physical output to real input. As such, they encompass a family of measures which include single factor input measures, such as output per unit of labor input (output per hour) or output per unit of capital input, as well as measures of multifactor productivity (output per unit of labor and capital inputs combined). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the value of goods and services in constant prices produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the value of goods and services in constant dollars produced per unit of capital services input.

Multifactor productivity is the ratio output per unit of labor and capital inputs combined. Changes in this measure reflect changes in a number of factors which affect the production process such as changes in technology, shifts in the composition of the labor force, changes in capacity utilization, research and development, skill and efforts of the work force, management, and so forth. Changes in the output per hour measures reflect the impact of these factors as well as the substitution of capital for labor.

Compensation per hour is the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, and the wages, salaries, and supplementary payments for the self-employed (except for nonfinancial corporations in which there are no self-employed)—the sum divided by hours paid for. **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current dollar value of output and dividing by output. **Unit nonlabor costs** contain all the components of unit nonlabor payments *except* unit profits.

Unit profits include corporate profits and the value of inventory adjustments per unit of output.

Hours of all persons are the total hours paid of payroll workers, self-employed persons, and unpaid family workers.

Capital services is the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Labor and capital inputs combined are derived by combining changes in labor and capital inputs with weights which represent each component's share of total output. The indexes for capital services and combined units of labor and capital are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Output measures for the business sector and the nonfarm business sector exclude the constant dollar value of owner-occupied housing, rest of world, households and institutions, and general government output from the constant dollar value of gross national product. The measures are derived from data supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are developed from data of the Bureau of Labor Statistics and the Bureau of Economic Analysis.

The productivity and associated cost measures in tables 42–44 describe the relationship between output in real terms and the labor time and capital services involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input. Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; capital investment; level of output; utilization of capacity, energy, and materials; the organization of production; managerial skill; and the characteristics and efforts of the work force.

Additional sources of information

Descriptions of methodology underlying the measurement of output per hour and multifactor productivity are found in the BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 13. Historical data for selected industries are provided in the Bureau's *Handbook of Labor Statistics*, 1985, Bulletin 2217.

INTERNATIONAL COMPARISONS
(Tables 45–47)

Labor force and unemployment

Description of the series

Tables 45 and 46 present comparative measures of the labor force, employment, and unemployment—approximating U.S. concepts—for the United States, Canada, Australia, Japan, and six European countries. The unemployment statistics (and, to a lesser extent, employment statistics) published by other industrial countries are not, in most cases, comparable to U.S. unemployment statistics. Therefore, the Bureau adjusts the figures for selected countries, where necessary, for all known major definitional differences. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country.

Definitions

For the principal U.S. definitions of the **labor force**, **employment**, and **unemployment**, see the Notes section on EMPLOYMENT DATA: Household Survey Data.

Notes on the data

The adjusted statistics have been adapted to the age at which compulsory schooling ends in each country, rather than to the U.S. standard of 16 years of age and over. Therefore, the adjusted statistics relate to the population age 16 and over in France, Sweden, and from 1973 onward, Great Britain; 15 and over in Canada, Australia, Japan, Germany, the Netherlands, and prior to 1973, Great Britain; and 14 and over in Italy. The institutional population is included in the denominator of the labor force participation rates and employment-population ratios for Japan and Germany; it is excluded for the United States and the other countries.

In the U.S. labor force survey, persons on layoff who are awaiting recall to their job are classified as unemployed. European and Japanese layoff practices are quite different in nature from those in the United States; therefore, strict application of the U.S. definition has not been made on this point. For further information, see *Monthly Labor Review*, December 1981, pp. 8–11.

The figures for one or more recent years for France, Germany, Great Britain, Italy, and the Netherlands are calculated using adjustment factors based on labor force surveys for earlier years and are considered preliminary. The recent-year measures for these countries are, therefore, subject to revision whenever data from more current labor force surveys become available.

Additional sources of information

For further information, see *International Comparisons of Unemployment*, Bulletin 1979 (Bureau of Labor Statistics, 1978), Appendix B and unpublished Supplements to Appendix B available on request. The statistics are also analyzed periodically in the *Monthly Labor Review*. Additional historical data, generally beginning with 1959, are published in the *Handbook of Labor Statistics* and are available in unpublished statistical supplements to Bulletin 1979.

Manufacturing productivity and labor costs

Description of the series

Table 47 presents comparative measures of manufacturing labor productivity, hourly compensation costs, and unit labor costs for the United States, Canada, Japan, and nine European countries. These measures are limited to trend comparisons—that is, intercountry series of changes over time—rather than level comparisons because reliable international comparisons of the levels of manufacturing output are unavailable.

Definitions

Output is constant value output (value added), generally taken from the national accounts of each country. While the national accounting methods for measuring real output differ considerably among the 12 countries, the use of different procedures does not, in itself, connote lack of comparability—rather, it reflects differences among countries in the availability and reliability of underlying data series.

Hours refer to all employed persons including the self-employed in the United States and Canada; to all wage and salary employees in the other countries. The U.S. hours measure is hours paid; the hours measures for the other countries are hours worked.

Compensation (labor cost) includes all payments in cash or kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. In addition, for some countries, compensation is adjusted for other significant taxes on payrolls or employment (or reduced to reflect subsidies), even if they are not for the direct benefit of workers, because such taxes are regarded as labor costs. However, compensation does not include all items of labor cost. The costs of recruitment, employee training, and plant facilities and services—such as cafeterias and medical clinics—are not covered because data are not available for most countries. Self-employed workers are included in the U.S. and Canadian compensation figures by assuming that their hourly compensation is equal to the average for wage and salary employees.

Notes on the data

For most of the countries, the measures refer to total manufacturing as defined by the International Standard Industrial Classification. However, the measures for France (beginning 1959), Italy (beginning 1970), and the United Kingdom (beginning 1976), refer to manufacturing and mining less energy-related products and the figures for the Netherlands exclude petroleum refining from 1969 to 1976. For all countries, manufacturing includes the activities of government enterprises.

The figures for one or more recent years are generally based on current indicators of manufacturing output, employment, hours, and hourly compensation and are considered preliminary until the national accounts and other statistics used for the long-term measures become available.

Additional sources of information

For additional information, see the BLS *Handbook of Methods*, Bulletin 2134-1 (Bureau of Labor Statistics, 1982), chapter 16 and periodic *Monthly Labor Review* articles. Historical data are provided in the Bureau's *Handbook of Labor Statistics*, Bulletin 2217, 1985. The statistics are issued twice per year—in a news release (generally in May) and in a *Monthly Labor Review* article (generally in December).

OCCUPATIONAL INJURY AND ILLNESS DATA

(Table 48)

Description of the series

The Annual Survey of Occupational Injuries and Illnesses is designed to collect data on injuries and illnesses based on records which employers in the following industries maintain under the Occupational Safety and Health Act of 1970: agriculture, forestry, and fishing; oil and gas extraction; construction; manufacturing; transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. Excluded from the survey are self-employed individuals, farmers with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies.

Because the survey is a Federal–State cooperative program and the data must meet the needs of participating State agencies, an independent sample is selected for each State. The sample is selected to represent all private industries in the States and territories. The sample size for the survey is dependent upon (1) the characteristics for which estimates are needed; (2) the industries for which estimates are desired; (3) the characteristics of the population being sampled; (4) the target reliability of the estimates; and (5) the survey design employed.

While there are many characteristics upon which the sample design could be based, the total recorded case incidence rate is used because it is one of the most important characteristics and the least variable; therefore, it requires the smallest sample size.

The survey is based on stratified random sampling with a Neyman allocation and a ratio estimator. The characteristics used to stratify the establishments are the Standard Industrial Classification (SIC) code and size of employment.

Definitions

Recordable occupational injuries and illnesses are: (1) occupational deaths, regardless of the time between injury and death, or the length of the illness; or (2) nonfatal occupational illnesses; or (3) nonfatal occupational injuries which involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment (other than first aid).

Occupational injury is any injury such as a cut, fracture, sprain, amputation, and so forth, which results from a work accident or from exposure involving a single incident in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to environmental factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday cases are cases which involve days away from work, or days of restricted work activity, or both.

Lost workday cases involving restricted work activity are those cases which result in restricted work activity only.

Lost workdays away from work are the number of workdays (consecutive or not) on which the employee would have worked but could not because of occupational injury or illness.

Lost workdays—restricted work activity are the number of workdays (consecutive or not) on which, because of injury or illness: (1) the employee was assigned to another job on a temporary basis; or (2) the employee worked at a permanent job less than full time; or (3) the employee worked at a permanently assigned job but could not perform all duties normally connected with it.

The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked even though able to work.

Incidence rates represent the number of injuries and/or illnesses or lost workdays per 100 full-time workers.

Notes on the data

Estimates are made for industries and employment-size classes and for severity classification: fatalities, lost workday cases, and nonfatal cases without lost workdays. Lost workday cases are separated into those where the employee would have worked but could not and those in which work activity was restricted. Estimates of the number of cases and the number of days lost are made for both categories.

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses, or lost workdays, per 100 full-time employees. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Only a few of the available measures are included in the *Handbook of Labor Statistics*. Full detail is presented in the annual bulletin, *Occupational Injuries and Illnesses in the United States, by Industry*.

Comparable data for individual States are available from the BLS Office of Occupational Safety and Health Statistics.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration, respectively. Data from these organizations are included in BLS and State publications. Federal employee experience is compiled and published by the Occupational Safety and Health Administration. Data on State and local government employees are collected by about half of the States and territories; these data are not compiled nationally.

Additional sources of information

The Supplementary Data System provides detailed information describing various factors associated with work-related injuries and illnesses. These data are obtained from information reported by *employers* to State workers' compensation agencies. The Work Injury Report program examines selected types of accidents through an employee survey which focuses on the circumstances surrounding the injury. These data are not included in the *Handbook of Labor Statistics* but are available from the BLS Office of Occupational Safety and Health Statistics.

The definitions of occupational injuries and illnesses and lost workdays are from *Recordkeeping Requirements under the Occupational Safety and Health Act of 1970*. For additional data, see *Occupational Injuries and Illnesses in the United States, by Industry*, annual Bureau of Labor Statistics bulletin; BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 17; *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985), pp. 411–14; annual reports in the *Monthly Labor Review*; and annual U.S. Department of Labor press releases.

1. Labor market indicators

Selected indicators	1984	1985	1984		1985				1986	
			III	IV	I	II	III	IV	I	II
Employment data										
Employment status of the civilian noninstitutionalized population (household survey)[1]										
Labor Force participation rate	64.4	64.8	64.4	64.5	64.8	64.7	64.7	64.9	65.1	[illegible]

Private nonfarm	–	–	.8	1.2	1.2	1.1	1.3	.6	1.0	.9
Price data [1]										
Consumer Price Index (All urban consumers): All items	4.0	3.8	1.2	.3	1.0	1.1	.7	.9	-.4	.6
Producer Price Index										
Finished goods	1.7	1.8	-.5	.9	.0	.7	-1.4	2.5	-3.1	.3
Finished consumer goods	1.6	1.5	-.5	.8	-.3	.7	-1.4	2.5	-4.1	.2
Capital equipment	1.8	2.7	-.5	1.1	1.3	.4	-1.4	2.5	.2	.5
Intermediate materials, supplies, components	1.3	-.3	-.4	-.1	-.4	.2	-.5	.4	-2.9	-.8
Crude materials	-1.6	-5.8	-2.0	-1.2	-8.1	-2.1	-6.5	4.3	-7.6	-2.2
Productivity data [3]										
Output per hour of all persons:										
Business sector	2.3	1.0	-.3	-.1	.9	2.7	3.4	-3.2	3.3	-.3
Nonfarm business sector	1.8	.5	-.7	-.4	.3	1.8	2.2	-3.5	4.3	-.5
Nonfinancial corporations [4]	2.0	1.2	-1.6	1.1	.8	2.2	4.9	-2.8	-.5	-2.3

[1] Annual changes are December-to-December change. Quarterly changes are calculated using the last month of each quarter. Compensation and price data are not seasonally adjusted and the price data are not compounded.

[2] Excludes Federal and private household workers.

[3] Annual rates of change are computed by comparing annual averages. Quarterly percent changes reflect annual rates of change in quarterly indexes. The data are seasonally adjusted.

[4] Output per hour of all employees.

– Data not available.

3. Alternative measures of wage and compensation changes

Components	Quarterly average						Four quarters ended–

---

[1] Cost (cents-per-hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.

[2] Consist of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

[3] Consists of legislative, judicial, administrative, and regulatory activities.

[4] Includes, for example, library, social, and health services.

[1] The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the *Monthly Labor Review* Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.

25. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Quarterly average							
	1984	1985	1984		1985				1986	
			III	IV	I	II	III	IV	I	II
Specified adjustments:										
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:										
First year of contract	3.6	2.6	2.7	3.7	3.6	3.5	2.0	2.0	0.4	0.7
Annual rate over life of contract	2.8	2.7	3.1	2.0	2.7	3.4	3.0	1.4	1.3	1.6
Wage adjustments, settlements covering 1,000 workers or more:										
First year of contract	2.4	2.3	2.1	2.3	3.3	2.5	2.0	2.1	1.0	1.3
Annual rate over life of contract	2.4	2.7	2.6	1.5	3.2	2.8	3.1	1.9	1.6	2.0
Effective adjustments:										
Total effective wage adjustment [3]	3.7	3.3	1.2	.7	.7	.8	1.2	.5	.6	.7
From settlements reached in period	.8	.7	.2	.3	.1	.2	.2	.1	.0	.2
Deferred from settlements reached in earlier periods	2.0	1.8	.7	.2	.6	.5	.5	.2	.4	.6
From cost-of-living-adjustments clauses	.9	.7	.3	.2	.1	.1	.4	.1	.2	.0

---

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

p = preliminary.

26. Average specified compensation and wage adjustments, major collective bargaining settlements in private industry situations covering 1,000 workers or more during 4-quarter periods (in percent)

Measure	Average for four quarters ending–							
	1984		1985				1986	
	III	IV	I	II	III	IV	I	II
Specified total compensation adjustments, settlements covering 5,000 workers or more, all industries:

[1] Data do not meet publication standards.

p = preliminary.

27. Average effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more during 4-quarter periods (in percent)

Effective wage adjustment	Average for four quarters ending–						
	1984	1985				1986	
	IV	I	II	III	IV	I	II^p
For all workers:[1]							
Total	3.7	3.6	3.5	3.5	3.3	3.1	2.9
From settlements reached in period	.8	.7	.9	.9	.7	.6	.5
Deferred from settlements reached in earlier period	2.0	2.2	1.9	1.8	1.8	1.7	1.8
From cost-of-living-adjustments clauses	.9	.7	.7	.8	.7	.8	.7
For workers receiving changes:							
Total	4.4	4.5	4.2	4.3	4.1	4.0	3.8
From settlements reached in period	3.0	2.9	2.9	2.8	3.4	2.9	2.5
Deferred from settlements reached in earlier period	4.0	4.2	3.9	3.7	3.7	3.5	3.4
From cost-of-living-adjustments clauses	2.7	2.3	2.3	2.8	2.2	2.5	2.1

[1] Because of rounding total may not equal sum of parts.

p = preliminary.

28. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, State and local government collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		First 6 months 1986^p
	1984	1985	
Specified adjustments:			
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:			
First year of contract	5.2	4.2	6.7
Annual rate over life of contract	5.4	5.1	6.4
Wage adjustments, settlements covering 1,000 workers or more:			
First year of contract	4.8	4.6	6.1
Annual rate over life of contract	5.1	5.4	6.0
Effective adjustments:			
Total effective wage adjustment [3]	5.0	5.7	1.8
From settlements reached in period	1.9	4.1	0.6
Deferred from settlements reached in earlier periods	3.1	1.6	1.2
From cost-of-living-adjustment clauses	(4)	(4)	(4)

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

[4] Less than 0.05 percent.

p = preliminary.

29. Work stoppages involving 1,000 workers or more

Measure	Annual totals		1985				1986^p								
	1984	1985	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.
Number of stoppages:															
Beginning in period	62	54	11	6	3	2	4	3	2	4	6	11	13	10	5
In effect during period	68	61	20	20	13	9	7	7	8	8	10	15	24	22	16
Workers involved:															
Beginning in period (in thousands)	376.0	323.9	69.5	76.6	25.2	9.2	7.6	24.0	11.2	6.1	29.6	199.0	46.7	113.3	32.4
In effect during period (in thousands)	391.0	584.1	93.9	119.3	47.0	38.0	12.0	28.4	38.6	17.6	41.2	205.9	68.3	144.8	84.0
Days idle:															
Number (in thousands)	8,499.0	7,079.0	963.8	1,429.8	586.2	981.9	170.0	309.5	387.5	297.3	303.6	3,684.3	894.5	1,612.1	1,191.7
Percent of estimated working time[1]	.04	.03	.04	.06	.04	.03	.01	.02	.02	.02	.02	.07	.04	.07	.06

[1] Agricultural and government employees are included in the total employed and total working time; private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in "'Total economy' measure of strike idleness," *Monthly Labor Review*, October 1968, pp. 54-56.

[1] Area is generally the Standard Metropolitan Statistical Area (SMSA), exclusive of farms. L.A.-Long Beach, Anaheim, Calif. is a combination of two SMSA's, and N.Y., N.Y.-Northeastern N.J. and Chicago, Ill.-Northwestern Ind. are the more extensive Standard Consolidated Areas. Area definitions are those established by the Office of Management and Budget in 1973, except for Denver-Boulder, Colo. which does not include Douglas County. Definitions do not include revisions made since 1973.

[2] Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:

M - Every month.
1 - January, March, May, July, September, and November.
2 - February, April, June, August, October, and December.

[3] Regions are defined as the four Census regions.

The population size classes are aggregations of areas which have urban population as defined:

A-1 - More than 4,000,000.
A-2 - 1,250,000 to 4,000,000.
B - 385,000 to 1,250,000
C - 75,000 to 385,000.
D - Less than 75,000.

Population size class A is the aggregation of population size classes A-1 and A-2.

- Data not available.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Because each local index is a small subset of the national index, it has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error than the national index. As a result, local area indexes show greater volatility than the national index, although their long-term trends are quite similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in escalator clauses.

Australia	9.0	8.3	8.6	8.6	8.5	8.2	7.9	8.0	–
Japan	2.6	2.6	2.7	2.6	2.6	2.7	2.9	2.7	2.8
France	9.9	10.4	10.3	10.5	10.4	10.4	10.1	10.3	10.5
Germany	7.8	7.9	7.8	7.9	7.9	7.9	7.8	7.8	7.6
Great Britain	12.9	13.1	13.0	13.1	13.2	13.4	13.0	13.1	13.3
Italy	5.9	6.0	5.8	5.9	5.8	6.0	6.3	6.3	6.5
Sweden	3.1	2.8	3.0	3.0	2.9	2.8	2.7	2.8	2.6

[1] Quarterly rates are for the first month of the quarter.

[2] Major changes in the Italian labor force survey, introduced in 1977, resulted in a large increase in persons enumerated as unemployed. However, many persons reported that they had not actively sought work in the past 30 days, and they have been provisionally excluded for comparability with U.S. concepts. Inclusion of such persons would more than double the Italian unemployment rate shown.

– Data not available.

NOTE: Quarterly figures for France, Germany, and Great Britain are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures.

46. Annual data: Employment status of the civilian working-age population, ten countries

48. Occupational injury and illness incidence rates by industry, United States

Industry and type of case[1]	Incidence rates per 100 full-time workers[2]								
	1976	1977	1978	1979	1980	1981	1982	1983	1984
PRIVATE SECTOR[3]									
Total cases	9.2	9.3	9.4	9.5	8.7	8.3	7.7	7.6	8.0
Lost workday cases	3.5	3.8	4.1	4.3	4.0	3.8	3.5	3.4	3.7
Lost workdays	60.5	61.6	63.5	67.7	65.2	61.7	58.7	58.5	63.4
Agriculture, forestry, and fishing[3]									
Total cases	11.0	11.5	11.6	11.7	11.9	12.3	11.8	11.9	12.0
Lost workday cases	4.7	5.1	5.4	5.7	5.8	5.9	5.9	6.1	6.1
Lost workdays	83.3	81.1	80.7	83.7	82.7	82.8	86.0	90.8	90.7
Mining									
Total cases	11.0	10.9	11.5	11.4	11.2	11.6	10.5	8.4	9.7
Lost workday cases	5.8	6.0	6.4	6.8	6.5	6.2	5.4	4.5	5.3
Lost workdays	114.4	128.8	143.2	150.5	163.6	146.4	137.3	125.1	160.2
Construction									
Total cases	15.3	15.5	16.0	16.2	15.7	15.1	14.6	14.8	15.5
Lost workday cases	5.5	5.9	6.4	6.8	6.5	6.3	6.0	6.3	6.9
Lost workdays	105.0	111.5	109.4	120.4	117.0	113.1	115.7	118.2	128.1
General building contractors:									
Total cases	14.5	15.0	15.9	16.3	15.5	15.1	14.1	14.4	15.4
Lost workday cases	5.2	5.7	6.3	6.8	6.5	6.1	5.9	6.2	6.9
Lost workdays	100.0	100.2	105.3	111.2	113.0	107.1	112.0	113.0	121.3
Heavy construction contractors:									
Total cases	16.3	16.0	16.6	16.6	16.3	14.9	15.1	15.4	14.9
Lost workday cases	5.5	5.7	6.2	6.7	6.3	6.0	5.8	6.2	6.4
Lost workdays	109.2	116.7	110.9	123.1	117.6	106.0	113.1	122.4	131.7
Special trade contractors:									
Total cases	15.3	15.6	15.8	16.0	15.5	15.2	14.7	14.8	15.8
Lost workday cases	5.6	6.1	6.6	6.9	6.7	6.6	6.2	6.4	7.1
Lost workdays	105.8	115.5	111.0	124.3	118.9	119.3	118.6	119.0	130.1
Manufacturing									
Total cases	13.2	13.1	13.2	13.3	12.2	11.5	10.2	10.0	10.6
Lost workday cases	4.8	5.1	5.6	5.9	5.4	5.1	4.4	4.3	4.7
Lost workdays	79.5	82.3	84.9	90.2	86.7	82.0	75.0	73.5	77.9
Durable goods									
Lumber and wood products:									
Total cases	22.1	22.3	22.8	20.7	18.6	17.6	16.9	18.3	19.6
Lost workday cases	9.7	10.4	11.1	10.8	9.5	9.0	8.3	9.2	9.9
Lost workdays	167.3	178.0	178.8	175.9	171.8	158.4	153.3	163.5	172.0
Furniture and fixtures:									
Total cases	16.9	17.2	17.5	17.6	16.0	15.1	13.9	14.1	15.3
Lost workday cases	6.0	6.0	6.9	7.1	6.6	6.2	5.5	5.7	6.4
Lost workdays	94.5	92.0	95.9	99.6	97.6	91.9	85.6	83.0	101.5
Stone, clay, and glass products:									
Total cases	16.1	16.9	16.8	16.8	15.0	14.1	13.0	13.1	13.6
Lost workday cases	6.4	6.9	7.8	8.0	7.1	6.9	6.1	6.0	6.6
Lost workdays	114.1	120.4	126.3	133.7	128.1	122.2	112.2	112.0	120.8
Primary metal industries:									
Total cases	16.6	16.2	17.0	17.3	15.2	14.4	12.4	12.4	13.3
Lost workday cases	6.3	6.8	7.5	8.1	7.1	6.7	5.4	5.4	6.1
Lost workdays	114.8	119.4	123.6	134.7	128.3	121.3	101.6	103.4	115.3
Fabricated metal products:									
Total cases	18.9	19.1	19.3	19.9	18.5	17.5	15.3	15.1	16.1
Lost workday cases	6.8	7.2	8.0	8.7	8.0	7.5	6.4	6.1	6.7
Lost workdays	109.8	109.0	112.4	124.2	118.4	109.9	102.5	96.5	104.9
Machinery, except electrical:									
Total cases	14.2	14.0	14.4	14.7	13.7	12.9	10.7	9.8	10.7
Lost workday cases	4.6	4.7	5.4	5.9	5.5	5.1	4.2	3.6	4.1
Lost workdays	70.6	69.9	75.1	83.6	81.3	74.9	66.0	58.1	65.8
Electric and electronic equipment:									
Total cases	8.5	8.6	8.7	8.6	8.0	7.4	6.5	6.3	6.8
Lost workday cases	2.8	3.0	3.3	3.4	3.3	3.1	2.7	2.6	2.8

---

[1] Total cases include fatalities.

[2] The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as: (N/EH) X 200,000, where:

N = number of injuries and illnesses or lost workdays.

EH = total hours worked by all employees during calendar year.

200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year.)

[3] Excludes farms with fewer than 11 employees since 1976.

Employee Benefits in Medium and Large Firms, 1985

U.S. Department of Labor
Bureau of Labor Statistics
July 1986

Bulletin 2262

The Bureau of Labor Statistics issues its 1985 Bulletin on employee benefits in medium and large firms. This survey is the seventh in an annual series.

Data available

- Incidence and detailed characteristics of 14 private sector employee benefits paid for at least in part by the employer: Lunch and rest periods, holidays, vacations, and personal, funeral, jury duty, military, and sick leave; sickness and accident, long-term disability, health, and life insurance; and private retirement/capital accumulation plans. Included in the retirement data is information on defined benefit plans, such as benefit formulas and pension replacement rates, and on defined contribution plans, such as salary reduction or 401 (k) plans.
- Incidence data on 17 other employee benefits, including financial counseling, prepaid legal services, and child care.

Coverage

- Major benefits in medium and large firms, nationwide.
- Minimum employment in establishments covered is generally 100 or 250 employees, depending on the industry.

Source of data

- Sample of about 1,500 establishments in a cross-section of the Nation's private industries; primarily by personal interview.

Uses

- Union contract negotiations.
- Conciliation and arbitration in public and private sectors.
- Development of legislation affecting the welfare of workers.

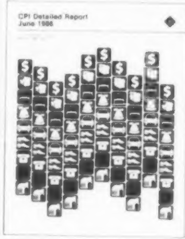
BLS Periodical Prices Reduced

BLS periodicals provide timely information on employment, occupations, wages, and prices. Subscriptions now are available at greatly reduced prices. In addition, newly available 2-year subscriptions guarantee the low prices for the next 2 years.

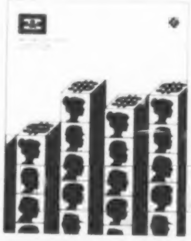
Monthly Labor Review
the oldest and most authoritative Government research journal in economics and social sciences. Regular features include current labor statistics and developments in industrial relations.
$16
~~$24~~ a year

Current Wage Developments
reports monthly on specific wage and benefit changes from collective bargaining agreements. Includes data on strikes or lockouts, major agreements expiring, and compensation changes.
$12
~~$21~~ a year

Occupational Outlook Quarterly
helps students and guidance counselors learn about new occupations, training opportunities, salary trends, and career counseling programs. Written in nontechnical language and illustrated in color.
$5
~~$11~~ a year



CPI Detailed Report
is the most comprehensive report on monthly consumer price indexes and rates of change.
$16
~~$25~~ a year



Employment and Earnings
gives current monthly employment and earnings statistics for the Nation as a whole, for States and for more than 200 areas. Included are household and establishment data seasonally and not seasonally adjusted. Includes annual supplement.
$22
~~$31~~ a year

Producer Price Indexes
Data for July 1986

Producer Price Indexes
includes monthly price movements of both farm and industrial commodities, by industry and stage of processing. Includes annual supplement.
$21
~~$29~~ a year

MONTHLY LABOR REVIEW

DECEMBER 1986
VOLUME 109, NUMBER 12

Henry Lowenstern, Editor-in-Chief
Robert W. Fisher, Executive Editor

Jerome A. Mark 3 **Measuring single-factor and multifactor productivity**

Development of new data sources, better use of existing sources, and broader coverage are some of the ways in which BLS has improved its productivity measures

Arthur Neef 12 **International trends in productivity, labor costs in manufacturing**

U.S. output per hour exceeded the rates of gain in 8 of 11 other industrial nations in 1985, but U.S. unit labor costs rose 2.7 percent relative to dollar-adjusted, trade-weighted average

Lawrence J. Fulco 18 **U.S. productivity growth: the post-recession experience**

Productivity increases for the current upturn are more modest than those recorded for similar postwar periods, although the manufacturing sector is performing well

Norman C. Saunders 23 **Sensitivity of BLS economic projections to exogenous variables**

The 1995 macroeconomic model has been most responsive to changes in fiscal spending and foreign economic activity; energy assumptions have had little effect on the estimates

Labor Month In Review

JOB SAFETY REPORT. The Bureau of Labor Statistics reported results of its survey of work-related injuries and illnesses in 1985. The report shows that job-related injuries and illnesses occurred at virtually the same rate in 1985 as in the previous year. The injury and illness rate was 7.9 per 100 full-time workers in 1985, compared with 8.0 in 1984. While the number of injuries and illnesses rose from 5.4 million in 1984 to 5.5 million in 1985, the rate remained stable because of increases in the number of employees and hours of work.

In releasing the new data, Commissioner of Labor Statistics Janet L. Norwood called the survey both comprehensive and well-designed, but expressed concern about the completeness of the recordkeeping upon which the survey is based. Norwood reported that BLS has taken the following steps to address this problem:

- BLS has revised and clarified the recordkeeping guidelines to provide better explanations to employers and workers about reporting obligations under the law. Nearly 400,000 copies of revised guidelines have been distributed. The Bureau also has launched an extensive effort to increase understanding of the requirements through seminars and other training activities.
- BLS has scientifically selected a sample and is providing other technical assistance to the Occupational Safety and Health Administration for a special pilot survey involving on-site evaluation of the records in 100 establishments in each of two States. BLS will evaluate the results of the survey.
- BLS has asked the National Academy of Sciences' Committee on National Statistics to establish a panel of experts to review the entire safety and health statistics system. BLS has requested that the panel make recommendations on techniques to evaluate the accuracy of recordkeeping as well as methods to develop more comprehensive statistical estimates of occupational illnesses.

The BLS survey data show that in 1985 there were 3,750 work-related deaths in establishments with 11 or more employees—about the same number as that in 1984. Two-thirds of all fatalities occurred in construction, manufacturing, and transportation and public utilities industries. As in previous years, the leading cause of death was over-the-road motor vehicle accidents, accounting for nearly one-third of fatalities in 1985.

Occupational injuries. Occupational injuries occurred at a rate of 7.7 per 100 full-time workers during 1985. About 46 percent of the recorded injuries were serious enough to require injured workers to take time off from work or to be restricted in work activity beyond the day of injury. While the overall injury rate was about the same in 1985 as in 1984, there was a marked decrease in injury rates in mining industries—from 9.5 in 1984 to 8.3 in 1985. In contrast, the injury rate increased in service industries—from 5.0 in 1984 to 5.3 in 1985. Injury rates varied by establishment size in 1985, as they have in previous years. Injury rates for small and large private sector establishments continued to be lower than the rate for mid-size establishments.

Occupational illnesses. The number of occupational illnesses measured by the annual survey is the number of new illness cases occurring during a year, not the prevalence of existing illnesses.

During 1985, there were about 125,000 new cases of these occupational illnesses among workers in private industry. More than two-thirds of these new cases involved skin diseases or disorders associated with repeated trauma (for example, noise-induced hearing loss and conditions due to repeated motion, pressure, or vibration). Chronic and long-term latent illnesses, which are often difficult to recognize or relate to the workplace, are included in the estimate but may be understated.

The distribution of illnesses among industries remained consistent with patterns of previous years. About 72,000 illness cases, or about 58 percent of the total, occurred in manufacturing, more than double the ratio of manufacturing employment to private sector employment.

Background of the survey. The Annual Survey of Occupational Injuries and Illnesses is a Federal/State program in which reports are received and processed by State agencies participating with the Bureau of Labor Statistics. The 1985 survey, requiring mandatory response, involved a sample of 280,000 establishments. The estimates generated from the survey represent the work injury and illness experience of over 81 million workers in the private sector of the American economy.

Data are based on the records which employers maintain under the Occupational Safety and Health Act of 1970. Excluded from coverage under the Act are workplaces which are covered by other Federal safety and health laws. Therefore, data conforming to definitions of recordable occupational injuries and illnesses for coal, metal, and nonmetal mining and railroad activities were provided to the Bureau by the Mine Safety and Health Administration of the U.S. Department of Labor and the Federal Railroad Administration of the U.S. Department of Transportation.

Also excluded from the survey are the self-employed; farmers with fewer than 11 employees; private households; and employees in Federal, State, and local government agencies. In a separate reporting system, agencies of the Federal Government file work injury and illness reports with the Secretary of Labor.

The fatality data only represent units with 11 or more employees, while estimates for the other types of cases (injuries and illnesses) include establishments with fewer than 11 employees.

A relative standard error is calculated for each estimate generated from the Annual Survey of Occupational Injuries and Illnesses and will be published in a BLS bulletin that is in preparation. □

Problems encountered in measuring single- and multifactor productivity

Development of new data sources, better utilization of existing sources, and broader coverage are some of the ways in which BLS has improved its productivity measures; progress has been made, but inadequacies remain

JEROME A. MARK

The slowdown in productivity growth since the early 1970's in many countries has stimulated and renewed interest in the causes of productivity change. The observation that there has been a slowdown has generally centered on the traditional indicator of productivity—output per unit of labor input, or labor productivity.

Labor productivity—the relationship between output and labor input—has been the most prevalent measure of productivity for a variety of reasons. First, labor is involved in all aspects of production and generally has been the most important factor in the production process. Second, labor input is the most readily measurable of the various production factors.

Labor productivity measures are useful in that they provide quantitative indicators of the amount of change in labor expended to produce real goods and services of an enterprise, industry, or economy. Changes in output per hour, however, do not measure the specific contribution of labor or any other factor of production. Instead, they reflect the joint effects of many influences which affect the use of labor, including changes in technology, capital investment, utilization of capacity, economies of scale, energy substitution, organization of production, and managerial skills, as well as changes in the characteristics and efforts of the work force.

To provide insights into some of the factors influencing labor productivity changes, other measures of productivity have been developed which include additional inputs, such as capital services and intermediate items (purchased materials, fuels, and business services). The difference in the movements of these multifactor productivity measures and the output per hour measures provides a look at the effect of the substitution of other factors on labor productivity movements. The multifactor measures themselves reflect changes in the use of many factors of production per unit of output over time.

The problems in developing multifactor productivity measures are much more severe than those present in deriving the traditional single-factor productivity measures. All the difficulties of defining and measuring output and labor input in the labor productivity measures are present in the development of the multifactor measures. But the additional problems of defining and quantifying the other inputs, such as capital, energy, and other intermediate inputs, are vastly more complex. This article discusses some of the problems the Bureau of Labor Statistics has encountered in developing productivity measures and explains the approaches taken to solve them.

Derivation of output

The output indexes for the measures of labor and multifactor productivity for the private business economy and its major sectors are derived from data on real gross product published in the National Income and Product Accounts (hereafter, national accounts) by the Bureau of Economic

---

Jerome A. Mark, Associate Commissioner for Productivity and Technology, Bureau of Labor Statistics, presented a paper on this subject at the International Productivity Symposium 2 in Munich, Germany, October 14–16, 1986. This article is based on that paper.

Analysis, U. S. Department of Commerce. Output measures for the detailed industries at the SIC (Standard Industrial Classification) two-, three-, and four-digit levels are prepared from basic data developed by various public and private agencies, using the greatest level of detail available.

Several major issues must be examined in the derivation of the output measures. These involve (1) selecting the appropriate output concept to be measured, (2) adjusting output so that it is consistent with available input measures, (3) obtaining quantity data on production, (4) developing appropriate weights for aggregating heterogeneous items into a single output measure, and (5) separating value change into price change and real output change.

The output concept used for the business and major sector measures is a net output or a value-added type of measure. The concept used for industries is a gross output measure that includes the value of purchased goods and services.

In using the national accounts data to derive the output measure for the business economy, several important exclusions from the gross national product (GNP) measures are made. These exclusions are necessary because (1) no adequate corresponding labor or capital input measure can be developed for some components of the national accounts, and (2) the gross product measures for some components are based on labor inputs implying constant output per unit of labor input.

Private business, which accounts for about 80 percent of GNP, includes the output of all activities measured in the national accounts, except for general government, paid employees of private households, nonprofit institutions, the "rest of world" sector, owner-occupied dwellings, government enterprises, and the statistical discrepancy.

General government is excluded because of the manner in which it is measured in the national accounts: The constant-dollar output of general government is derived by adjusting base-year hourly compensation for changes in the total hours of government employees. This assumes that productivity of this component remains constant. Private household employees and nonprofit institutions are also excluded for this reason.

The "rest of world" sector is excluded primarily for reasons of consistency between output and input data. The current value of output of this sector is equal to the payments to factors (labor and capital) abroad owned by U.S. residents, less payments to factors in the United States owned by foreigners. The payments to factors abroad owned by U.S. residents cannot be related to corresponding labor and capital inputs. The returns to income sent abroad to foreign owners of U.S. enterprises should be included but are not, to provide consistency between the output and input data.

Owner-occupied dwellings are also excluded for consistency purposes. In the national accounts, an estimate is made for the rental value of owner-occupied housing for inclusion in the GNP measures. The output of this service, the net rental value of owner-occupied homes, is estimated as the amount for which owner-occupied homes could be rented, less maintenance, insurance, and like expenses. However, there is no measure available for the hours worked by homeowners.

Statistical discrepancy is the difference between GNP estimates constructed from the product (the sum of all production for consumption, investment, government, and net foreign trade) and the income (the sum of all income resulting from compensation, profits, interest, and so forth) sides of the national accounts. Given that the input data are more closely related to the income side of the accounts, measures net of statistical discrepancy are developed to provide greater consistency between the output and input data.

Government enterprises—the U.S. Postal Service, the Tennessee Valley Authority, State and local enterprises, and the like—are excluded from the multifactor productivity measures because only limited data are available on their capital input. In the national accounts, structures and durable equipment used by these enterprises are treated as final sales to general government rather than as investments of the enterprises. Government enterprises thus show no capital cost associated with plant and equipment in the national accounts. Data on labor input of these enterprises, however, are available and the output of these enterprises is included in the labor productivity measures.

The aggregate measure resulting from these adjustments covers the product of the private business sector. Included in the output measure for this sector, however, are national accounts data for some miscellaneous items still based on measures of their inputs. This results from use of hourly compensation indexes or cost indexes as a deflator in the national accounts. Use of these measures implies no productivity change for the associated components. These remaining items, however, do not constitute a serious problem because they amount to only 6 percent of the total. (See table 1.)

Specific problems. Although GNP data are adjusted to make them appropriate for the multifactor productivity series, there are still problems with the measures. Perhaps the most important is the adequacy of the price measures used to derive the constant-dollar measures. The price measures used in the national accounts to deflate the value of output and intermediate inputs are predominantly from components of the consumer and producer price indexes prepared by BLS.

In obtaining the data for these series, respondents are asked to quote prices for clearly specified items. When producers significantly alter a product, they are asked to report the changes so BLS can adjust the reported price to reflect the change in quality based on the additional cost (or saving) due to the change. However, a quality change in a product can be achieved in ways which are not captured by measuring the cost of the change, either because there is no way to identify the direct cost associated with a specific

Table 1. Relationship between gross national product and the BLS measure of private business sector gross product, 1985

Item	Amount (billions of 1982 dollars)	Percent
Gross national product (GNP)	$3,585.2	100
Output items excluded from GNP to obtain BLS private business gross product:		
General government	355.5	10
Owner-occupied housing	209.4	6
Rest-of-the-world	37.0	1
Households and institutions	140.0	4
Government enterprises	43.9	(1)
Statistical discrepancy	−5.0	(1)
BLS private business gross product	2,804.4	78
Value of output deflated by hourly compensation or cost indexes	238.5	6
Nonresidential structures	152.2	4
Other	86.3	2
Value of output deflated by output price indexes	2,565.9	72

change, or because there is no additional cost involved.

Two items have been particularly weak in the price area: the treatment of computers and the derivation of construction industry measures.

Because of the rapid changes that have been taking place and the inability to obtain reliable data in price surveys, the national accounts, for many years, assumed no change in the price of computers. It was generally believed that rapid changes in quality of the computers resulted in an upward bias in the prices and a downward bias in the resulting output and productivity measures.

To improve these measures, the Bureau of Economic Analysis, in conjunction with IBM, conducted a study in which new price measures for computers were developed.[1] This study compared two approaches: (1) a matched model index in which prices of models on the market in 2 adjacent years were used to compute a chain index over a period of years, and (2) hedonic indexes, computed using regressions showing the effects of specific computer characteristics on computer prices. A composite index was developed combining results from the two approaches. This composite index showed a substantial drop in the prices for computers and a corresponding increase in real output from that previously reported. While this measure is a considerable improvement, further development of the measurement technique for computer prices is being pursued.

In the construction area, developments have not been as fruitful. With the exception of single-family housing and highway construction, the price indexes available for construction activities are generally input price or cost indexes. (This problem is reflected in the entry for nonresidential structures in table 1.) The resultant productivity index for this industry has a bias toward no change and, to a lesser extent, this extends to the overall measure.

A hedonic price measure has been developed for single-family housing and a bid price index is used for highway construction. These price measures do reflect changes in the utilization of materials and labor per unit of output. They do not, however, represent a large proportion of total construction activities.

The output measures for the industry productivity indicators are derived independently of the national accounts. For each industry, the quantities of the various products that are produced by the industry are directly aggregated with the appropriate weights for the various products which make up the output of the industry. The appropriate weight for the direct aggregation of the products is the base-year factor input. Thus, for a labor productivity measure, the weight is the base-year hours of employees in the industry engaged in the production of each output. For a multifactor industry productivity measure, the appropriate weights for the output are the costs of the factor inputs. The resultant productivity measure is an internal mean of the productivity movements of the component elements of the industry. Thus, the labor productivity measure reflects the change in the labor expended in the production of a constant bundle of goods or services, and the multifactor measure reflects the change in all factors expended in the production of the bundle.

In some industries, however, unit employee hour information is not available for individual products. In such cases, substitute weights are used when it is believed that they are proportional to unit employee weights. These are either labor costs per unit of product, unit value added, or prices. The resultant productivity measure from any of these derivations reflects the effects of shifts in the labor cost, value added, or value per hour among the various products within the industry, as well as the change in productivity among the various products.

For some industries, data collected in the U.S. economic censuses have enabled the BLS to develop labor input weights for product classes, if not at the product level. Thus, a hybrid measure is developed which includes substitute (usually price) weights for combining specified products into product classes and labor weights beyond the product class level.

For those industries lacking quantity data, constant-dollar value of shipments data, adjusted for inventory change, are used to develop the output measure. Deflation of the value of the production of the industry by the price change of the various products is a variant of weighting the physical quantity data with unit values. The adequacy of these measures depends to a great extent on the adequacy of the price measures used to deflate the current-dollar value of output.

The problem of inadequate price deflators is more pronounced with the industry output measures. In many cases, its resolution largely determines whether a productivity measure can or cannot be derived. This has been one of the important factors determining the number of productivity measures that are available in the service sector. In recent years, the number of producer and consumer price indexes has been increasing substantially in the service area, as has the number of productivity measures developed.

In developing the deflated value of gross output indexes for SIC two-digit industries, it is useful to remove intraindustry transactions from the output series. Data for the transactions between establishments in the same two-digit industry are difficult to obtain. However, approximations can be obtained from input-output data.[2] For this purpose, the amount of imported goods included in intraindustry consumption is estimated and removed. Domestic consumption of materials produced by the same domestic industry is then divided by the total domestic commodity output and multiplied by gross output to estimate intraindustry sales. These are then subtracted from the two-digit industry deflated shipment data, adjusted for inventory change, to obtain the output measure.

Determining labor input

The labor input measures for both the sector and industry productivity series are based largely on a monthly survey of establishment payroll records. This survey, the BLS Current Employment Statistics program (establishment survey), provides data on total employment (for all employees) and average weekly hours (for production and nonsupervisory workers only) in nonagricultural establishments. Because the output of the goods and services reflects the activities of all persons engaged in economic activity, it is important to develop labor input measures that include the self-employed, unpaid family workers, and, for the total business sector, labor input on farms. These data are derived, for the most part, from a household survey of the noninstitutional population, the Current Population Survey, which is conducted by the Bureau of the Census for the BLS.

Reliance on establishment survey data provides major benefits, but also presents two problems. The major benefits derive mainly from the size and coverage of the survey: Payroll data are provided each month from a nationwide sample of more than 200,000 establishments. The problems are that the establishment hours are based on an hours paid, rather than an hours worked, concept, and the data exclude average weekly hours of nonproduction and supervisory workers.

A desirable measure of productivity is one that reflects the change in labor input actually involved in the productive process. The hours paid data include paid vacations, holidays, sick leave, and other paid time off, in addition to the actual hours worked. To the extent that leave practices change, the resultant productivity measures overstate or understate the actual change in output per hour or output per unit of labor and capital combined.

To develop a better series of hours at work, the BLS has been conducting an annual survey (now in its fifth year) of some 4,000 establishments to collect data on hours at work and hours paid for all production and nonsupervisory workers in the private nonagricultural business sector. From this survey, ratios are developed to adjust the hours paid measures from the establishment survey to an hours at work basis. The definition of hours at work was established, after careful study, as time on the job or at the place of work. Besides actual time at work, it includes coffee breaks, short rest periods, paid cleanup time, and other paid time at the workplace. This definition was considered to be conceptually the most acceptable one for which statistics could be extracted from establishment records. A narrower definition of hours actually worked was considered questionable and, in any case, too difficult to collect.

Although the problem of developing the appropriate hours concept for the productivity measures is being resolved at the level of the business economy and the major sectors, the current survey does not provide data in sufficient detail to enable the BLS to develop corresponding measures at the industry level.

In the absence of information from the establishment survey on the average weekly hours for nonproduction and supervisory workers, two solutions, neither entirely satisfactory, have been adopted. For average weekly hours of nonproduction workers in manufacturing, ratios of the average weekly hours of manufacturing office workers to those of nonoffice workers have been developed from surveys in the 1960's and 1970's. Estimates of average weekly hours of nonproduction workers in manufacturing are obtained by multiplying production worker hours by these ratios. In industries other than manufacturing, supervisory employees' average weekly hours are assumed to be equal to those of nonsupervisory workers.

The BLS measures of productivity based on the hours of all persons assume that workers are homogeneous with respect to skill. However, a highly skilled worker can be viewed as providing more labor services per hour than a lesser skilled worker. When skill differences are ignored, increases in skill levels are measured as increases in productivity. As a result, shifts from less skilled to more skilled labor because of increased education or on-the-job training are not reflected as an increase in the measure of labor input. For some purposes, it is useful to have a productivity measure that includes any changes in the potential productivity or quality of an input in the input measure. The problem is to construct a measure of labor input which accurately reflects changes in the skill level of the work force.

Worker characteristics weights

Previous studies have generally taken the position that relative wage or income level differentials associated with specific worker characteristics—years of schooling, age, sex, and possible industry and occupation—reflect marginal productivity of these attributes. Weighting the quality of labor (hours or employment), classified by these characteristics of the work force, by the relative wage or income differentials results in an aggregate measure of labor input intended to reflect the composition of the work force.

While this procedure certainly is not without merit, it presents some difficulties. In particular, it is not always clear whether certain characteristics are indeed productive. For example, workers with similar characteristics have widely different earnings in different occupations. However, this correlation between occupation and earnings may be due to influences other than the productivity of the occupation *per se*. Furthermore, wages or earnings may also be an imperfect indicator of marginal product because they may vary for reasons unrelated to productivity, including regional differences in the cost of living and various institutional factors.

To address these problems, the BLS is developing new measures of labor input based solely on changes in the amount of work experience and schooling workers acquire. This methodology, which follows directly from the economic theory of human capital as developed by Jacob Mincer and Gary Becker,[3] assumes that increased schooling and on-the-job training increases one's stock of skills, and thus one's productivity. Furthermore, the economic returns to higher education and additional work experience reflect the marginal productivity of these characteristics. The BLS has developed a multidimensional data base which cross-classifies the annual hours of workers grouped by schooling and experience. Simultaneously, the implicit prices of these characteristics have been calculated.

The determination of work experience requires substantial effort. There are no large-scale surveys which directly collect data on work experience. Instead, an econometric model has been developed that estimates an individual's quarters of work experience, based on available survey data regarding other personal characteristics. This model requires that for each year, the work force be cross-classified by age, sex, education, race, marital status, and number of children. For the decennial census years, and for years after 1968 when observation data from the household survey could be used, the cross-classification of the work force is straightforward. For the remaining years (1948, 1949, 1951–59, 1961–67), a multiproportional interpolation procedure is employed.

The experience model makes use of a matched sample developed from both the household survey and Social Security records. The results have proven to be significantly better than previous estimates: They show that there is a positive correlation between education and experience which some measures of experience do not take into account and which can produce biased estimates. This positive correlation is shown by a comparison of the derived returns to education and experience using the traditional estimates of experience and the new estimates.

As mentioned earlier, it is recognized that hourly wages differ not only because of skill differences, but also because of factors unrelated to productivity. Accordingly, simple averages of hourly wage rates for each education and experience group are not necessarily appropriate measures of marginal productivity. To remove these imperfections, another econometric model has been developed which provides measures of wages dependent upon changes in education and experience, but which simultaneously controls for other types of variation.

This model measures the returns to seven different schooling levels and to quarters of work experience. It controls for differentials by full- or part-time status, regional location, and urban or rural residence of a worker. The latter two variables adjust for possible regional price variations. Proprietors and unpaid family workers are excluded from the estimating sample because their income may reflect not only labor returns, but also returns to capital. The model is designed to yield returns to education and experience adjusted for the possible effects of race and sex discrimination on wages. Initially, annual measures of these returns will be constructed for the 1948–85 period.

The construction of aggregate measures of labor input requires that all hours be cross-classified by the level of education and the amount of experience for men and women separately. The hours of each type of cross-classified labor are weighted by the corresponding hourly rental price determined from the model above to obtain a Törnqvist weighted index of labor input. Skill-adjusted labor input measures are presently being developed for the business and nonfarm business sectors.

In sum, the measurement of labor input is limited in several problem areas. One is achieving more accurate coverage of hours of all persons; another is developing hours at work measures; and another is developing weights which reflect differentials in marginal productivity. Some success in each of these areas has been achieved at the macro level with measures for the business economy and major sectors. However, problems remain with the measures for individual industries. It is difficult to see possibilities for substantial improvement in industry measures without substantial expansions in the surveys providing the basic data.

Capital input measures

Capital inputs should be measures of the flow of services from capital stocks rather than of capital stocks themselves. This is consistent with the measurement of labor and output as flows of goods and services. It is also consistent with the general observation that it is the services of a physical asset, rather than the asset itself, that enter into the production process. Further, it permits the capital input measure to differentiate between the annual contributions of a short-lived asset and a long-lived asset that yields its services at a slower annual rate relative to its value as a stock.

The BLS measures adopt the service-flow concept. The assets included are fixed business equipment and structures, inventories, and land. Structures include nonresidential structures and residential capital which is rented out by profitmaking firms or persons. Financial assets are excluded, largely on pragmatic grounds, as are owner-occupied residential structures.

The capital input measures are constructed in two stages. First, stocks are estimated for various types of assets. The stock estimates are developed after assuming that an asset's services diminish in a fixed pattern as it ages. Second, assets are aggregated by weighting with capital income shares based on rental prices. This step requires the development of rental prices for each type of capital stock.

Exhibit 1 summarizes the methods and data sources used to construct the measures of capital input. Steps 1 through 5 correspond to the first stage and steps 6 and 7, the second.

The framework used for deriving the capital input measures is based on the concept that the stock of capital represents the amount of new investment that would be required to produce the same capital services actually produced by existing assets of all vintages. Thus, the stock measure requires historical data on real investment and assumes an age-efficiency function that describes the pattern of services that capital goods supply as they age.

The measures of investment form the initial point for deriving the capital stock measures. These are constant-dollar measures and are derived from price indexes which have limitations similar to those of indexes used in deriving the constant-dollar GNP output measures. For example, equipment is deflated principally by using the Producer Price Indexes. One part of investment equipment includes computers and, for many years, this presented a problem in measurement of this component of investment. The recently developed price measure for computers (discussed earlier) has improved the estimates for this component. Structures are deflated by indexes of residential prices, highway construction prices, and the construction cost indexes. The highway component and the tenant-occupied, single-family housing construction components are deflated by adequate price measures, but the other structures must be deflated by inadequate cost measures.

In general, the relationship between the economic efficiency of an asset and its age is very complex and depends on the particular type of asset as well as a host of other factors, such as the level of economic activity, relative input prices, interest rates, and technological developments.

Use of an efficiency function involves a strong assumption. The quantity of capital services from a particular asset is assumed to be a function of its age alone. Thus, because the pattern of diminishing services remains fixed over time, the resulting capital measure cannot respond to variations in factor demand. In view of this restrictive assumption, the validity of weighting with a function representative of age alone remains a major issue.

Several general forms have been employed, none of which is completely satisfactory. Use of the gross stock assumes that the asset exhibits no loss of services until it suddenly is discarded. Other forms are net of some loss of services during their lives. A straight-line form shows the same loss of services each year. A concave form shows gradual losses early in the life of an asset, and more rapid losses as it ages. A convex form shows rapid early losses followed by more gradual losses of the remaining efficiency.

Several attempts have been made to address the efficiency function issue by observing used asset prices. A relationship is postulated between the efficiency of a used asset and its market price relative to that of a new asset. The most extensive empirical study of used asset prices in the United States was done by Charles Hulten and Frank Wykoff in 1981.[4] BLS concluded that the concave deterioration pattern appeared to be consistent with the empirical data in the Hulten-Wykoff study, as well as with the reports of businesses concerning experiences with their own capital assets.[5]

Many private researchers have used alternative forms such as a gross measure with no deterioration, a geometric decay function with early rapid decline and a slackening of the rate of decline as the asset ages, other concave forms, and straight-line deterioration.[6] To test the impact of the choice of a particular function on the final measure of multifactor productivity, BLS conducted sensitivity tests of the growth rates of multifactor productivity and of the contribution of the capital-labor ratio to the growth in labor productivity using the different age-efficiency relationships. What emerged was that the choice of function had very little effect on either the multifactor productivity growth rates or the contribution of capital services per hour to the growth rates of output per hour. The largest difference in long-term productivity growth produced by the alternative functions was 0.1 percent. (See table 2.)

Depreciable assets have finite lives; eventually they are discarded from stock. Average lives of the different asset groups are based on recently revised estimates from the Department of Commerce. Asset lives are assumed to be normally distributed with a fairly wide dispersion to take account of the range of service lives observed within each investment cohort.

The second stage in constructing measures of capital services is the aggregation of capital stocks by weighting the stocks with income shares based on rental prices. The various types of capital assets are appropriately aggregated using implicit rental prices (sometimes called user costs) for each type of asset. The rental price represents the annual costs which would be incurred by an organizaiton that purchases an asset with the intention of renting it out.[7] Thus, the rental prices are implicit because the owners and users of capital assets are frequently the same.

Rental prices are calculated for each type of asset. Assets with shorter lives tend to have higher depreciation rates, and therefore, higher rental prices, and are given a larger weight in capital input. This implies that assets with higher rental prices contribute more to the annual flow of output than assets with lower rental prices.

The Törnqvist method is used to combine the capital series by asset type. The change in capital input is, in effect,

Table 2. Sensitivity of private business sector multifactor productivity measure to various age-efficiency assumptions, 1949–81

a weighted sum of the percentage changes in the capital inputs by asset type. The weights are developed as averages, for the current and preceding year, of the asset's capital compensation, which is the product of the asset's rental price and the quantity of its stock.

Stocks for inventories are based on average end-of-quarter real inventories as reported in the national accounts. The land stock estimate for the farm portion of private business, where land represents a large share of capital, is developed by aggregating regional acreage figures using weights reflecting regional rental values. In the nonfarm sector, the measure for land is derived by multiplying structures by a land-structures ratio.[8]

The capital input measures for the SIC two-digit industries are developed in the same manner as those for the major sectors. However, one problem is encountered at the two-digit level in implementation of the usual capital input measurement procedures. The capital rental price formulation includes the rate of return plus the rate of depreciation minus the rate of capital gains—inflation in the value of an asset—all in nominal terms. Rental prices are used to construct weights for asset types as discussed above. Capital gains are usually computed as the year-to-year change in the deflator for new investment.

At the two-digit level, some industries have very low rates of return in some years. After capital gains are subtracted, some rental prices are volatile over time and even negative. The resulting asset weights thus lead to implausible capital aggregates. Furthermore, this volatility clearly comes from asset-specific year-to-year movements in the deflators customarily used to determine capital gains. Because the derivation of the rental price assumes perfect foresight, the usual procedure of estimating capital gains implies, incorrectly, that investors fully anticipate even erratic price movements. After careful study, BLS concluded that the usual procedure of using an annual deflator is not required by theory.[9] A 3-year moving average of the deflator was judged superior on empirical grounds.

Intermediate inputs

Intermediate purchases include materials, fuels, and business services. Material inputs represent all commodity inputs exclusive of fuels (electricity, fuel oil, coal, natural gas, and miscellaneous fuels). Data on the total cost of materials are available from Department of Commerce annual surveys and are deflated by appropriate price indexes to obtain measures of real material inputs. Because the data are obtained on an establishment basis, products transferred between establishments in the same industry are included in the aggregate materials cost. A two-step procedure is used to determine the rate of growth in real expenditures for materials which are purchased from outside the particular industry. First, from the annual current-dollar cost of materials, an estimate of the cost of intraindustry sales and transfers is removed. Second, a materials deflator is constructed with the detailed materials price data and information on weights from input-output tables.

Data on the price and quantity of energy inputs are constructed from annual surveys. These include only the quantity and cost of fuels purchased for heat and power. However, quantity information is not available for all years, and the measures are extrapolated and interpolated using annual estimates of total cost deflated by appropriate Producer Price Indexes.

Directly collected data on purchased business services are relatively scant in the United States. Nevertheless, the inclusion of purchased services in the input measure is important because there is ample evidence of increased use by industries of such services. Also, there is evidence of increased substitution of leased capital for owned capital, and of purchased services such as accounting, legal, and technical services for services performed inhouse.

The BLS estimates these services from published input-output tables. The general approach is to take service shares in the value of production from the input-output tables at the greatest level of detail; to obtain service costs by multiplying the shares by the value of production; and to deflate these current cost estimates by appropriate deflators. Prices for service inputs are obtained from the consumer and producer price indexes or imputed from various data sources. This is a major problem which will be alleviated by developing more extensive price measures for the service activities.

Multifactor productivity

The calculation of multifactor productivity proceeds from dividing the index of output by the derived index of combined inputs. In the net, or value-added, output framework used in developing the measures for the private business economy and the major sectors, the combined inputs are labor (hours) and capital services. The aggregate input index

Exhibit 1. Summary of methods and data sources used to measure capital and multifactor productivity

Step	Data item obtained or constructed	Method used and detail in which step is performed	Data source
1. Obtain real investment data for data for depreciable assets	Investment in:		
	Equipment	20 asset types	National accounts[1]
	Structures	14 asset types	National accounts[1]
	Rental residential capital	9 asset types	National accounts[1]
2. Allocate investment data to major sectors	Investment by asset type by sector (farm manufacturing, nonfarm manufacturing)	Asset detail allocated using methods in step 1	See step 1
		Sectoral investment total proportional to national accounts	National accounts[1]
		Historical data cross-classified by asset detail and sector	National accounts[1]
3. Determine age/efficiency functions for each type of asset	Weights reflecting the declining services of an asset type cohort as it ages	A hyperbolic form using:	
		An average service life estimate	National accounts[1]
		Normal distribution of discards	National accounts[1]
		A shape determined using empirical evidence	Hulten and Wykoff[2]
4. Perform vintage aggregation	Real stocks of depreciable assets by type and sector	Perpetual inventory method: Real historical investments weighted by age/efficiency functions	See steps 2 and 3
5. Measure nondepreciable assets	Stock of inventories	By stage of processing in manufacturing	National accounts[1]
	Stock of farm land	Regional services weighted using rental prices	U.S. Department of Agriculture
	Stock of land in manufacturing and nonfarm manufacturing	Proportional to structures using benchmark land estimate	Allan[3]
6. Obtain constant rental prices	Implicit rental value of the services of a unit of each type of asset in each sector	Rental price formula estimated using data on capital stocks and data on payments to capital	Christensen and Jorgenson;[4] steps 4 and 5; and national accounts[1]
7. Obtain aggregate assets	Measure of real capital input in each sector	Törnqvist index to asset capital stocks using rental prices to determine weights	Steps 4, 5, and 6

[2] Shares were reconciled to functions reported in C. R. Hulten and F. C. Wykoff, "The Measurement of Economic Depreciation," in C. R. Hulten, ed., *Depreciation, Inflation and Taxation of Income from Capital* (Washington, The Urban Institute Press, 1981), pp. 81–125; and C. R. Hulten and F. C. Wykoff, "The Estimation of Economic Depreciation Using Vintage Asset Prices," *Journal of Econometrics*, 1981, pp. 367–96.

[3] Benchmarks based on estimates from Manvel D. Allan, "Trends in the Value of Real Estate and Land, 1956–1966," *Three Land Research Studies* (Washington, National Commission on Urban Problems, 1966).

[4] Formula used to measure rental prices derived by Laurits R. Christensen and Dale W. Jorgenson, "The Measurement of U.S. Real Capital Input, 1929–1967," *Review of Income and Wealth*, December 1969, pp. 292–320.

is derived by weighting the annual growth rates of the individual components, where the weights are the income shares of each component averaged over the current and preceding year, a Törnqvist index. Within each sector, total income is equal to the sum of labor compensation of all employees (labor income), corporate property income (capital income), and proprietors' income.

The labor compensation data for employees are readily available from the national accounts. However, proprietors' income is the total return to the proprietors' own labor *and* capital. Because this income reflects returns to both factors of production, it is necessary to develop a method to allocate the income between the two factors.

Various assumptions can be made to do this. For example, production worker earnings can be imputed to the self-employed, but this frequently results in negative nonlabor proprietor income (which is obtained as a residual). Conversely, the rate of return on capital in the corporate sector can be applied to the proprietors' capital, but this frequently yields negative proprietors' labor income.

In the BLS measures, proprietor hours are given the same average wages received by paid employees, and capital income is measured by assigning noncorporate capital the same rate of return as corporate capital. The sum of these computed values is compared with reported noncorporate income in the national accounts, and both the derived labor and capital income are scaled to agree with the reported levels.

The combined input index, then, is derived by weighting the labor input index by the derived compensation share of total income, and the capital input index by the income share of capital.

In the derivation of the two-digit industry and the specific industry multifactor measures, the output measure is a gross output index including the value of purchased materials and services. The corresponding factor input measure reflects intermediate materials and purchased services as well as the labor and capital inputs. These are combined with share weights also; in this case, the sum of the labor, capital, and intermediate shares will equal one.

Inadequacies remain, despite progress

Measurement of productivity change is not a simple task. Despite recent progress, it is clear that inadequacies remain in the data available for measurement of both labor and multifactor productivity. In addition, multifactor productivity measurement presents challenging problems of shaping sometimes imperfect data into empirical measures that take advantage of recent theoretical advances. While multifactor productivity measures are useful for understanding factors affecting the traditional productivity movements, and many such measures have been developed, it is important to recognize that they do not have the same degree of precision that the labor productivity measures have. In estimating them, many more assumptions have to be made, particularly with regard to measuring capital input.

Despite problems, improvements in the measures have been made and, undoubtedly, more will follow. For example, better price data for developing constant-dollar output and capital and intermediate material input measures are now available. Better estimates of rental prices for aggregating the heterogeneous capital stocks have been developed. Even the output per hour measures are being improved using more appropriate hours information and developing adjustments for changes in the composition of the work force.

Improvements in the procedures for measuring productivity must and will continue to be made. Productivity measures of high quality can shed light on policy issues of great importance, including questions on the best means of increasing the efficiency of economic resources, the ability of the economy to expand without adding to inflationary pressures, and the determinants of a country's competitive position in international markets. □

[7] The foundations for the use of rental prices in asset aggregation were set forth in Laurits R. Christensen and Dale W. Jorgenson, "The Measurement of U.S. Real Capital Input, 1929–1967," *Review of Income and Wealth*, December 1969, pp. 292–320. Their analysis proceeds from the assumption of equilibrium of supply and demand in the rental market and develops a rental price equation. Rental prices derived from this equation are assumed to reflect the stock's marginal products. The equation reflects, among the determinants of rental prices, depreciation costs, and the rate of return in the form of interest and profits. These costs are reduced by inflation in the value of the asset and adjusted for tax considerations.

International trends in productivity and unit labor costs in manufacturing

U.S. output per hour exceeded the rates of gain in 8 of 11 other industrial countries in 1985, but U.S. unit labor costs rose 2.7 percent relative to the trade-weighted average of the other nations after adjustment for the dollar's appreciation

ARTHUR NEEF

Labor productivity, as measured by output per hour, rose 4.4 percent in manufacturing in the United States in 1985. This exceeded the rates of gain recorded by Canada and 7 of 9 European countries studied—France, Italy, the United Kingdom, Denmark, the Netherlands, Norway, and Sweden. However, two major trade competitors, Japan and West Germany, along with Belgium, had larger increases.

Manufacturing output rose in each country, but the increases recorded by the United States and most of the other countries were substantially less than in the preceding year and only Canada, Japan, Denmark, and Norway had increases in both employment and aggregate hours.

Unit labor costs, which reflect changes in productivity and hourly compensation costs, rose less in the United States, at 0.6 percent, than in Canada or in the seven European countries with smaller productivity gains. Germany and Belgium, however, had about equally small increases, and unit labor costs fell in Japan. The relative value of the U.S. dollar began to fall during 1985, but on an annual average basis the U.S. dollar was up by 0.4 percent over 1984 compared with the Japanese yen, by 5 percent compared with the Canadian dollar, and by 2 to 9 percent compared with the European currencies. Consequently, when measured on a U.S. dollar basis, unit labor costs declined in Belgium, Canada, Germany, Italy, and the Netherlands, as well as in Japan. Only the three Scandinavian countries had larger increases than the United States. Measured on a national currency basis, U.S. unit labor costs fell 0.5 percent relative to a trade-weighted average of the other 11 countries; adjusted for the dollar's appreciation, U.S. relative unit labor costs rose 2.7 percent.

This article examines comparative annual average percent changes in manufacturing labor productivity and labor costs through 1985 in the United States and 11 other industrial nations.[1] The comparisons are limited to trend measures only; reliable level comparisons of manufacturing productivity and unit labor costs are not available.[2] The measures for 1985 are preliminary. Data for other years are also subject to some revision as countries revise the underlying statistics used to construct the measures.[3] The Canadian productivity and labor cost series are in the process of being revised because of a benchmark revision of the Canadian national accounts, including a shift in the base year from 1971 to 1981 for the series at constant prices, and a major historical revision in the labor income series. The revised measures were not available for inclusion in this article.[4]

The article also provides comparisons of changes in U.S. manufacturing productivity and labor costs relative to a trade-weighted average of the 11 other countries. The relative measures were constructed by taking the ratio of the U.S. indexes to weighted geometric averages of the corresponding indexes for the other 11 countries. The weights used to combine the other 11 countries' indexes into an average "competitors" index reflect the relative importance of each country as a manufacturing trade competitor as of 1980.[5]

Arthur Neef is chief of the Division of Foreign Labor Statistics, Bureau of Labor Statistics. He was assisted by Division economists Harry Boissevain, Christopher Kask, and James Thomas.

Productivity trends

The U.S. productivity gain of about 4½ percent in 1985 was somewhat stronger than the average trade-weighted gain of 4 percent recorded by the 11 foreign competitor nations, although below the 5- to 5½-percent increases recorded by Japan and Germany. (See table 1.) In the 3 years from 1982 to 1985, the U.S. average increase of 4.7 percent was about equal to the average 5-percent increase of the 11 foreign nations, most of which had average annual gains between about 4 and 5½ percent. On the upside, Japan and the Netherlands registered nearly 6 and 7 percent and on the downside, Denmark and Norway posted 1.5 and 3 percent.

As pointed out in previous articles,[6] all 12 countries have had productivity slowdowns since about 1973 as compared with the period 1960 to 1973. The addition of 1985 data does not change this pattern. However, the U.S. productivity gains for each of the 3 years between 1982 and 1985 exceeded the U.S. average rate of gain between 1960 and 1973. The United Kingdom was the only other country to exceed its pre-1973 rate over the 1982–85 period.

Output and labor input. U.S. manufacturing output growth slowed from 11 percent in 1984 to about 4 percent in 1985. (See table 2.) Most of the other countries also had smaller output gains in 1985 than in the preceding year. A notable exception was Germany, where output rose 5 percent—Germany's largest annual increase since 1976.

The slowdown in U.S. manufacturing output growth did not result in a lower rate of productivity growth because total worker hours, which rose 6½ percent in 1984, were reduced by 0.5 percent in 1985. (See table 3.) This has not been typical of the United States, where manufacturing output increases of 2 percent or more are normally accompanied by increases in employment and hours. It corresponds more closely to recent developments in many of the European countries, where employment and hours have frequently continued to decline even in years of relatively large output increases. In 1985, however, total manufacturing hours rose along with output in Denmark and Norway and remained about unchanged in Sweden and the United Kingdom. Employment rose strongly in Denmark and increased in Germany, the Netherlands, Norway, and Sweden. Employment and hours also rose in Canada and Japan, but at reduced rates from 1984.

The rise in Dutch manufacturing employment was the first annual increase since 1970; the increase in Norwegian employment was the first since 1977. British employment remained nearly stable after falling in 9 of the previous 10 years. However, employment in Belgium and France continued to fall for the 11th consecutive year. The tabulation below shows the peak year for manufacturing employment in each of the 12 countries and the level of employment in 1985 relative to the peak employment year and relative to 1973. The latter was one of very large output increases in each country, but not the peak employment year for any country.

	Peak employment year	*1985 index*	
		Peak = 100	*1973 = 100*
Japan	1985	100	101
Canada	1979	95	100
United States	1979	92	96
Denmark	1965	92	94
Italy	1974	87	89
Norway	1974	85	88
Sweden	1965	84	89
Germany	1970	81	83
France	1974	81	82
Netherlands	1965	70	76
Belgium	1974	65	66
United Kingdom	1966	64	70

Hourly compensation and unit labor costs

Hourly compensation costs—which include wages and salaries, supplements, and employer payments for social security and other employee benefit plans—rose 2½ percent between 1984 and 1985 in Japan; about 5 to 6 percent in the United States, Canada, France, Germany, Belgium, Denmark, and the Netherlands; and 7 to 10 percent in Italy, the United Kingdom, Norway, and Sweden. As shown in table 4, all countries recorded slower increases in 1985 compared with their 1973–85 trend rates.

Japan, which had the largest increases in hourly compensation in the 1960's and among the largest increases in the

NOTE: Rates of change based on the compound rate method.

first half of the 1970's, has had the smallest average rate of increase in the 1980's—about 4 percent. The only other countries with average gains of 6 percent or less since 1980 are the United States, Germany, and the Netherlands.

Unit labor costs, which reflect changes in both labor productivity and hourly compensation, fell for the fourth consecutive year in Japan as productivity continued to climb more than hourly compensation. Manufacturing unit labor costs were about unchanged in 1985 in Belgium. Unit labor costs rose only about 0.5 percent in the United States and Germany. In the previous 2 years, unit labor costs fell 3 percent in the United States and rose only 0.5 percent in Germany. Canada and the other European countries had 1985 increases of 2 to 7 percent.

Unit labor costs in U.S. dollars

Unit labor costs measured in U.S. dollars were significantly influenced by 1985 changes in currency exchange rates, as they were in the previous 4 years. The value of the U.S. dollar began to fall during 1985 relative to the Japanese yen and the European currencies, but measured on an annual average basis, the U.S. dollar was largely unchanged relative to the yen and rose about 2 to 5 percent relative to the currencies of Canada and all of the European countries except Italy. The dollar rose 8 percent relative to the Italian lira. Consequently, manufacturing unit labor costs on a U.S. dollar basis declined in Canada, Germany, Italy, Belgium, and the Netherlands as well as in Japan. On a national currency basis, 8 of the 11 foreign countries had larger unit labor cost increases than the United States; on a U.S. dollar basis, only the three Scandinavian countries had larger increases.

The strong gain of the U.S. dollar relative to most other currencies began about 1980. As of 1985 (annual average),

NOTE: Rates of change based on the compound rate method.

the Japanese yen was only 5 percent below its 1980 value. However, the Canadian dollar was down to 86 percent of its 1980 value, relative to the U.S. dollar, and the European currencies ranged between about 45 and 60 percent of their 1980 values. The following tabulation shows the effect of these exchange rate changes by comparing the average annual percentage changes in each country's unit labor costs between 1980 and 1985, as measured on a national currency basis and on a U.S. dollar basis:

	National currency	*U.S. dollars*
United States	2.1	2.1
(Trade-weighted average, 11 countries)	3.1	−4.3
Canada	5.4	2.1
Japan	−1.2	−2.3
Norway	7.0	−4.2
Italy	11.9	−4.7
Denmark	6.2	−6.5
United Kingdom	3.9	−7.6
Germany	1.8	−7.6
France	7.4	−7.7
Sweden	5.5	−8.4
Netherlands	.1	−9.7
Belgium	1.2	−12.2

Expressed in national currencies, 7 of the 11 foreign countries had greater increases in unit labor costs than the United States. Taking into account the appreciation of the dollar since 1980, only one country besides the United States—Canada—had an increase in unit labor costs.

Unadjusted for exchange rate changes, Japan improved its relative competitive position more than any of the other 11 countries, with an overall decline in unit labor costs between 1980 and 1985. However, because of the sharp relative depreciations of all of the European currencies, all nine European countries had larger declines in unit labor costs than Japan after adjustment for relative changes in exchange rates. The countries that most improved their competitive positions were those with small increases in unit labor costs in national currency terms and large relative currency depreciations, such as Belgium and the Netherlands. Table 5 shows annual percent changes in U.S. unit labor costs, average trade-weighted "competitors" unit labor costs, and the U.S. relative measures.

Recent exchange rate changes

The comparative measures in this article are based on annual average measures. Therefore, the 1985 trend measures of unit labor costs on a national currency basis have been adjusted to a U.S. dollar basis using annual average exchange rates for 1985. As noted earlier, the U.S. dollar in 1985 was largely unchanged relative to the Japanese yen on an annual average basis and rose between 2 and 9 percent relative to the currencies of the other 10 countries. However, by the end of 1985, the U.S. dollar had depreciated strongly against the yen and most European currencies and the dollar continued to depreciate during 1986. Table 6 provides a comparison of October 1986 exchange rates and

NOTE: Rates of change based on the compound rate method.

January-October 1986 exchange rates relative to annual average 1985 and 1980 exchange rates.

As the table shows, while the Canadian dollar continued to depreciate slightly, the Japanese yen as of October 1986 had risen 52 percent in value relative to the U.S. dollar over the annual average of 1985 and the European currencies were up 10 to 46 percent. Whether U.S. relative unit labor costs will fall in 1986 in line with the depreciation of the U.S. dollar will, of course, depend on comparative 1986 developments in productivity and hourly compensation costs. As of the first three quarters of 1986, U.S. manufacturing unit labor costs were up only 0.3 percent over the first three quarters of 1985.

While the relative values of the Japanese yen and the European currencies rose strongly in 1986, only the Japanese yen has increased in value over 1980. The relative values of the European currencies, which in 1985 ranged between 45 and 60 percent of their 1980 values, ranged between 60 and 90 percent of their 1980 values as of October 1986.

Exchange rates and trade. Because of the 1985–86 depreciation of the U.S. dollar, many commentators have expected significant improvement in the U.S. trade balance. However, two important facts are often overlooked. The U.S. dollar has not depreciated against the Canadian dollar, and Canada accounted for 20 percent of U.S. manufactured imports, for 25 percent of U.S. manufactured exports, and for 12 percent of the U.S. trade deficit in manufactured products in 1985. Of possibly greater significance, the U.S. dollar has not depreciated against the currencies of most of the Asian and Latin American countries or areas that are frequently referred to as the newly industrializing countries—such as Hong Kong, Singapore, South Korea, Taiwan, Brazil, and Mexico. Table 6 also shows exchange rate indexes for these 6 countries and areas, along with 1985 U.S. trade weights (percent of U.S. imports and exports of manufactured goods) and percent of the U.S. trade deficit in manufactured goods for the 6 and for the 11 foreign coun-

[1] Percent of total U.S. imports and exports of manufactured goods in 1985, excluding special category exports (military goods sent out under Department of Defense contracts). Weight for Belgium is Belgium-Luxembourg combined.

[2] Percent of U.S. trade deficit in manufactured goods in 1985. See footnote 1.

[3] Not relevant unless adjusted for inflation.

tries covered by the comparative unit labor cost measures.

The six newly industrializing countries and areas accounted for 18 percent of U.S. trade in manufactured goods in 1985 and for 25 percent of the trade deficit in manufactured products. For comparison, the nine European countries covered by this article accounted for 22 percent of U.S. trade and 20 percent of the deficit. As of October 1986, the relative value of the Taiwan dollar was up moderately against the U.S. dollar but the Hong Kong and Singapore dollars and the South Korean won were little changed from their 1985 values. The relative values of the currencies of Brazil and Mexico were only about half of their average 1985 values as of October 1986, but, in large part, this reflects sharply higher prices. A more meaningful comparison among countries with markedly different price developments is a real exchange rate index, that is, one adjusted for relative differences in inflation. Inflation-adjusted exchange rate indexes for Brazil and Mexico (1985=100) were, respectively, 108 and 82 in the first half of 1986.

The principal trade-weighted dollar exchange rate indexes are those published by the Board of Governors of the Federal Reserve System, the Department of the Treasury, the International Monetary Fund, and the Morgan Guaranty Trust Co. of New York. All of these indexes show a sharp depreciation of the U.S. dollar since early 1985, but, while all four indexes include Canada, they all exclude the six newly industrializing countries and areas of Asia and Latin America. An exchange rate index including these countries was recently developed by senior economist W. Michael Cox of the Federal Reserve Bank of Dallas.[7] His index, which covers 131 U.S. trading partners, shows only a 6-percent depreciation of the U.S. dollar between March 1985 and May 1986, while the other four indexes show depreciations ranging from about 18 percent up to 34 percent.[8] The differentials between the Cox index and the other four would probably be less on an inflation-adjusted basis. An inflation-adjusted index computed by Cox shows a 7-percent depreciation of the U.S. dollar between the first and fourth quarters of 1985, compared with a nominal 2-percent depreciation over the same period.[9] □

—FOOTNOTES—

[1] The data relate to all employed persons, including the self-employed, in the United States and Canada, and to all wage and salary employees in the other countries. Hours refer to hours paid in the United States and to hours worked in the other countries.

[2] The Bureau does not prepare level comparisons of manufacturing productivity and unit labor costs because of data limitations and technical problems in comparing the levels of manufacturing output among countries. Each country measures total manufacturing output in its own currency units. To compare outputs among countries, a common unit of measure—such as the U.S. dollar—is needed. However, satisfactory conversion factors are not available for the manufacturing sector. Market exchange rates are not suitable as a basis for comparing output levels. What are needed are purchasing-power-parity (PPP) exchange rates, that is, the number of foreign currency units required to buy goods and services equivalent to what can be bought with one unit of U.S. currency. Reasonably reliable PPP exchange rates are available for total gross domestic product (GDP) and are used by the Bureau for comparing levels of total GDP. See Michael Ward, *Purchasing Power Parities and Real Expenditures in the OECD* (Paris, Organization for Economic Cooperation and Development (OECD), 1985); and Peter Hill, *International Price Levels and Purchasing Power Parities*, OECD Economic Studies No. 6 (Paris, OECD, Spring 1986). However, these PPP exchange rates are derived from the expenditure side of the national accounts (consumer, business, and government final expenditures for goods and services) and not from the output side of the accounts (gross product originating by industry). Therefore, they do not provide PPP exchange rates by industry. Some researchers have published level comparisons of manufacturing productivity using either the PPP exchange rate for total GDP or a constructed PPP exchange rate based on selected final expenditures by consumers and businesses. However, there are large differences in PPP exchange rates for different categories of final expenditure and the author is not aware of any satisfactory justification for the use of either procedure for comparing manufacturing output levels, although a constructed PPP exchange rate that excludes government consumption expenditures and consumer expenditures on services should provide a better approximation of a PPP exchange rate for the manufacturing sector than the PPP for total GDP.

[3] This article includes revised statistics which have not yet been incorporated in "Current Labor Statistics," table 47, this issue.

[4] The output figures from 1981 forward will be based on 1981 price weights. The figures for earlier years will continue to be based on 1961 and 1971 price weights, although they will be expressed in 1981 constant dollar levels. This contrasts with the U.S. method; when the U.S. national accounts were rebased to 1982, the entire constant dollar series was revised.

[5] The trade weights were adapted from weights developed by the International Monetary Fund (IMF). The original IMF weights cover 17 countries; the 11 foreign countries covered by this article account for 94 percent of the IMF 16 U.S. competitors' total trade weight. For more information on the relative indexes, see Patricia Capdevielle, Donato Alvarez, and Brian Cooper, "International trends in productivity and labor costs," *Monthly Labor Review*, December 1982, pp. 3–14.

[6] For example, see Edwin Dean, Harry Boissevain, and James Thomas, "Productivity and labor cost trends in manufacturing, 12 countries," *Monthly Labor Review*, March 1986, pp. 3–10.

[7] See W. Michael Cox, "A New Alternative Trade-Weighted Dollar Exchange Rate Index," *Economic Review*, Federal Reserve Bank of Dallas, September 1986, pp. 20–28. In addition to introducing the new index, the article provides a comparison with the four principal indexes. Cox's index differs from the other four primarily by its much broader coverage—131 countries versus 10 to 22 countries. It also differs in that he uses annually moving rather than constant trade weights. Both the 1985 and 1986 indexes are based on 1985 weights, but the 1986 indexes will be revised when full-year 1986 trade data become available. During the period when the dollar was appreciating strongly, the five indexes show more similar results—a U.S. dollar appreciation between January 1980 and March 1985 ranging from 42 percent up to Cox's 65.5 percent.

For another recently compiled trade-weighted dollar exchange rate index that includes the major newly industrializing countries and areas, see Irwin L. Kellner "Why Our Trade Gap Persists," *Manufacturers Hanover Economic Report*, September 1986. Kellner's index covers the 17 largest U.S. trading partners and uses 1985 weights. It shows only about a 4-percent trade-weighted depreciation of the U.S. dollar between February 1985 and August 1986.

[8] March 1985 to April 1986 for the Treasury index. All of the other four indexes include Canada, but with very different weights. As reported in Cox, the weights given to Canada are 9 percent in the Board of Governors index, 30 percent in the Morgan Guaranty Trust index, and 21 percent in the International Monetary Fund and his own index (1985 weight).

[9] Information provided directly to the author by W. Michael Cox. Cox's article did not include an inflation-adjusted index.

The Morgan Guaranty Trust Co. publishes both nominal and real effective U.S. dollar exchange rates. They show virtually the same U.S. dollar depreciation—24.0 and 24.7 percent, respectively, between March 1985 and July 1986.

U.S. productivity growth since 1982: the post-recession experience

Gains in productivity during recoveries typically are greater than the long-term trend; increases for the current upturn are more modest than those recorded for similar postwar periods, although the manufacturing sector is performing well

LAWRENCE J. FULCO

Productivity in the business sector has grown at an average annual rate of 2.3 percent since 1947.[1] Growth was more rapid before 1973 (3.0 percent) than after (0.9 percent), but throughout the postwar period, the business cycle has had pronounced effects on the rate of change in productivity. Table 1 shows these effects on productivity growth in the business, nonfarm business, and manufacturing sectors.

There have been eight business cycle troughs since the end of World War II, the most recent of which occurred in the fourth quarter of 1982.[2] (See exhibit 1.) The business cycle exerts an accelerating influence on productivity growth during recoveries and retards it during contractions. Since the 1982 trough, the BLS has analyzed movements in labor productivity—output per hour of all persons—for purposes of comparing this recovery with similar periods in the past.

The cycle's effect on productivity is often explained in terms of the fixed nature of some inputs in the short run. Because the stocks of capital plant and equipment and the number of available skilled employees are not instantaneously adjustable, they remain to some extent fixed over the course of the cycle. Thus, when product demand increases after a trough, firms are able to increase output more rapidly than capital and labor inputs, thereby inducing a swift rise in productivity. During a contraction the opposite occurs, giving rise to a procyclical pattern in productivity.

Productivity in the business sector[3] has risen more rapidly during postwar recoveries (2.6 percent per year) than over the entire 1947–85 period (2.3 percent). The same is true for the more narrowly defined nonfarm business and manufacturing sectors. However, since the beginning of the productivity slowdown in 1973, the contrast between productivity advances during recoveries and the long-term trend in productivity increase has become greater. Since 1973, the growth rate during recoveries has been more than 0.6 percent higher than the long-term rate for business and nonfarm business, and 1.1 percent higher for manufacturing. In manufacturing, the post-1973 slowdown has been smaller than in the more comprehensive business and nonfarm business sectors. (Manufacturing accounts for about one-fourth of the business sector output.)

The current recovery

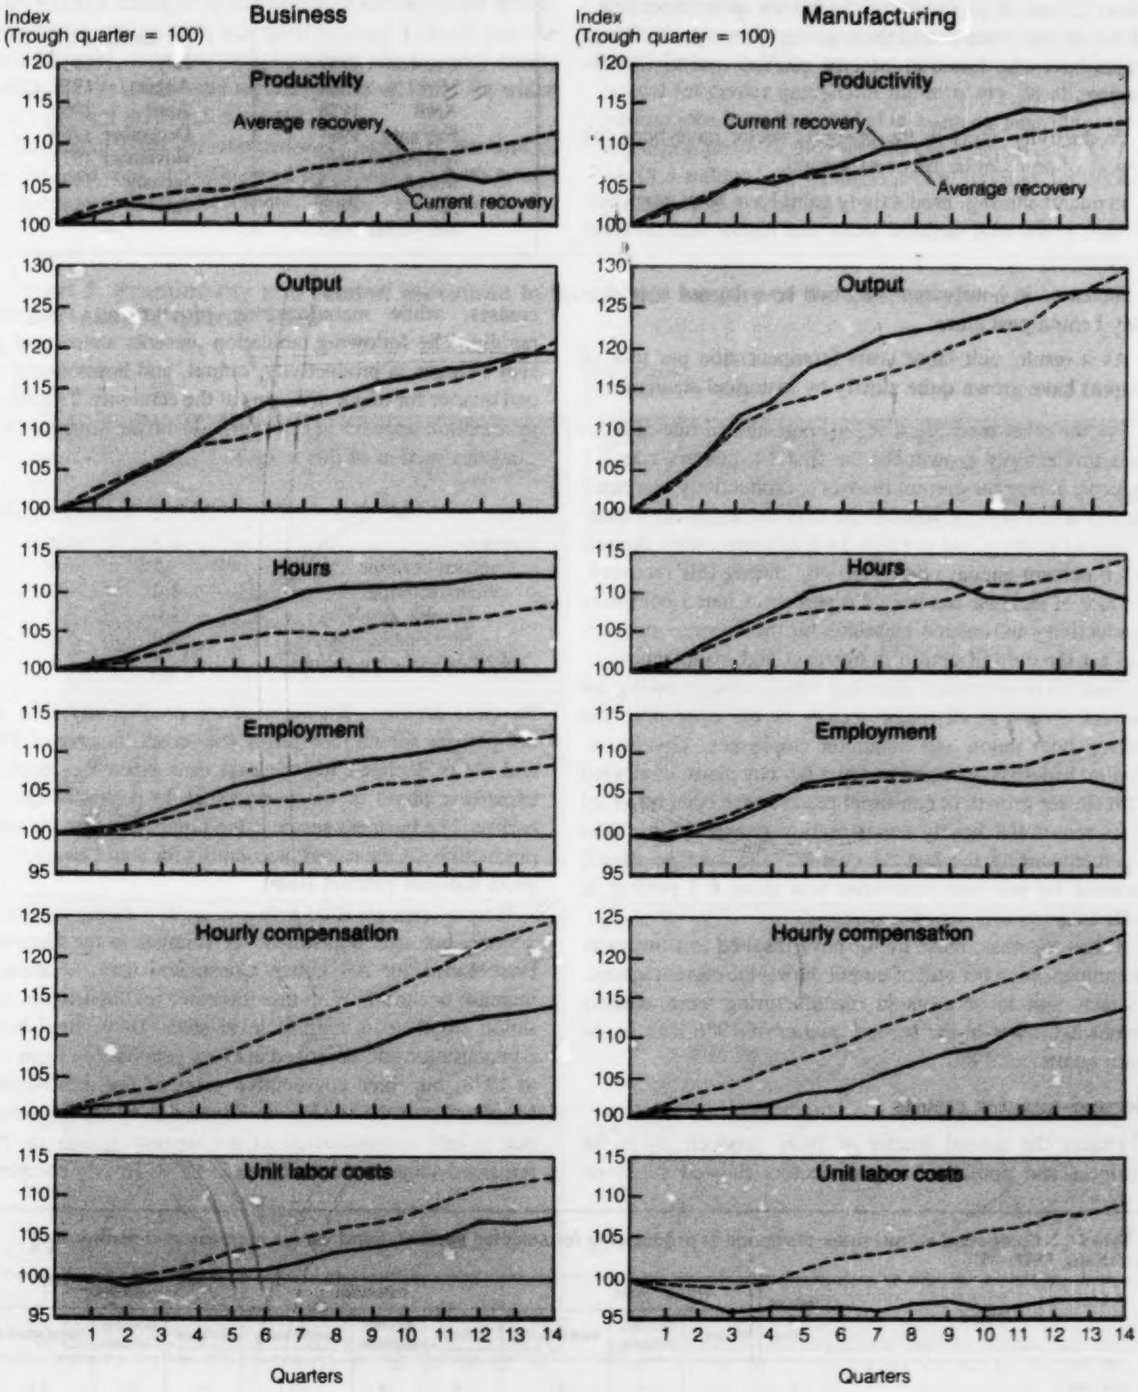
The eight postwar recoveries are dissimilar, ranging in length from 4 to 35 quarters, trough to peak:

Trough	*Quarters, trough to peak*
October 1949	15
May 1954	13
April 1958	8
February 1961	35
November 1970	12
March 1975	20
July 1980	4
Mean	15

By the second quarter of 1986, the current recovery had lasted 14 quarters, longer than all but three of the others.

Lawrence J. Fulco is a supervisory economist in the Office of Productivity and Technology, Bureau of Labor Statistics.

Chart 1. Productivity and related measures 14 quarters after the trough of the business cycle in the business and manufacturing sectors, current recovery versus average postwar recovery



Because recoveries have differed so widely, it is not possible to draw any conclusions regarding the underlying growth rate of productivity based on experience during this part of the cycle. (For similar reasons, projections of the future course of productivity change are quite unreliable.) However, a comparison of the ongoing recovery with others which have also lasted at least 14 quarters reveals the following:

- Productivity gains in the business sector have been the lowest of any similar recovery period.
- In manufacturing, productivity gains have been much better than in the total business sector and higher than previous experience.
- Increases in hourly compensation have lagged considerably behind past gains.
- As a result, unit labor costs (compensation per unit of output) have grown quite slowly by historical standards.

For the other recoveries, the average annual rate of business productivity growth for the first 14 quarters was 3.1 percent; during the current recovery, productivity increased at only a 1.8-percent annual rate over the same time span. In manufacturing, the average 14-quarter recovery showed a 3.6-percent annual rate of growth; during this recovery, the rate of increase has been 4.4 percent. Chart 1 compares productivity and related measures for the average recovery and for the current upturn in business and manufacturing.

Hourly compensation gains have been modest during the current upturn in all major sectors of the economy, and among both union and nonunion employees. Givebacks, smaller benefits packages, and two-tier pay plans, combined with slower growth in consumer prices, have been reflected in current-dollar hourly compensation growth of less than 4 percent during the last 14 quarters; the average annual increase for previous recoveries was about 6.5 percent in both business and manufacturing.

Taken together, these trends have resulted in slow gains in compensation per unit of output during the current upturn. In fact, unit labor costs in manufacturing were actually somewhat lower in the second quarter of 1986 than in the third quarter of 1980.

Exhibit 1. Troughs and peaks of the eight postwar business cycles

Trough	Peak
—	November 1948
October 1949	July 1953
May 1954	August 1957
April 1958	April 1960
February 1961	December 1969
November 1970	November 1973
March 1975	January 1980
July 1980	July 1981
November 1982	—

Second-quarter results

During the second quarter of 1986, productivity in the business and nonfarm business sectors showed slight increases, while manufacturing productivity rose more rapidly. The following tabulation presents annualized percent changes in productivity, output, and hours in the second quarter for major divisions of the economy. (Additional information appears in tables 42–44 of the Current Labor Statistics section of this issue.)

Sector	*Productivity*	*Output*	*Hours*
Business	0.5	0.3	−0.2
Nonfarm business	.5	.6	.1
Manufacturing	3.2	−.4	−3.5
Durable goods	1.0	−3.8	−4.8
Nondurable goods	7.0	5.3	−1.6
Nonfinancial corporations	−.3	−1.1	−.8

Business sector. Business sector productivity rose at a 0.5-percent annual rate during the second quarter of 1986, and hours declined for the first time since the recovery-expansion phase of the business cycle began 14 quarters earlier. The business sector is the broadest sector for which productivity is measured, accounting for about four-fifths of gross national product (GNP).

Hourly compensation rose moderately during the second quarter, but after adjustment for changes in the Consumer Price Index for All Urban Consumers (CPI-U),[4] a strong increase occurred. With this increase, real hourly compensation stood at its highest level since 1979. Real hourly compensation had advanced in every year but one from 1947 to 1978, but three consecutive years of declines occurred beginning with 1979. Growth resumed in 1982, but even so, real hourly compensation in the second quarter of 1986 remained somewhat lower than in 1978. Hourly compensa-

Table 1. Compound annual rates of change in productivity for selected sectors, trend versus recovery and contraction phases, 1947–85

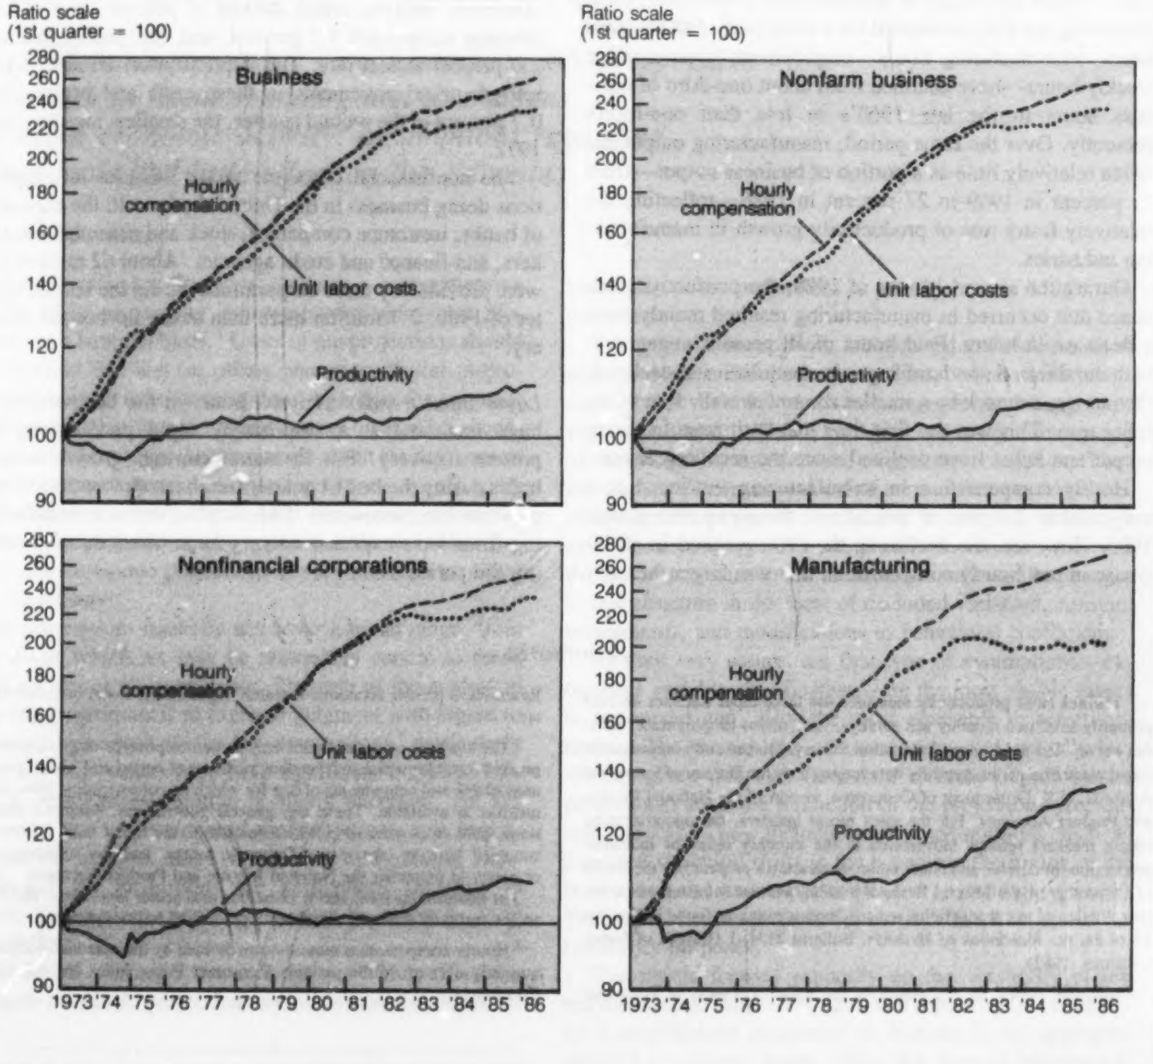
Period	Number of cycles	Trend			Contraction			Recovery		
		Business	Nonfarm business	Manufacturing	Business	Nonfarm business	Manufacturing	Business	Nonfarm business	Manufacturing
1947–1985	8	2.3	1.9	2.7	.6	.4	−.1	2.6	2.1	3.3
1947–1973	5	3.0	2.5	2.9	1.3	1.1	−.2	3.1	2.6	3.3
1973–1985	3	.9	.7	2.2	−.7	−.7	.0	1.7	1.3	3.3

tion includes wages and salaries, supplements, and employer payments to employee benefit plans, and measures employer costs rather than employee income. Adjustment with the CPI-U translates these costs into real terms, by taking into account changes in the prices of consumption goods. The decline in the CPI-U was quite unusual in itself; over the past 25 years, there has only been one other quarter during which the CPI-U fell—the second quarter of 1961, for which a 0.1-percent drop was recorded.

Unit labor costs are compensation expenses per unit of output, and thus are influenced by changes in both hourly compensation and productivity. In the second quarter of 1986, these important costs rose at an annual rate of only 2.3 percent. This small increase reflects the slow gains in hourly compensation which have characterized the entire recovery period and the small productivity gain in the second quarter, as shown in chart 2.

Business employment continued to grow during the second quarter of 1986, but the pace was slower than was typical for earlier quarters of the recovery. In all, over 9.5 million jobs have been added to business payrolls since the expansion phase of the business cycle began early in 1983. At 88.4 million, the business sector accounts for about 77 percent of U.S. employment.

Chart 2. Productivity and related measures in four major sectors of the economy, 1973–second quarter 1986



Nonfarm business. Productivity movements in nonfarm business are, of course, not affected by developments on farms, which are included in the more comprehensive business measure. Nonfarm productivity showed the same increase as the business measure in the second quarter. Output rose more than in the business sector, and hours posted a small rise. These were the smallest increases in nonfarm output and hours during the current expansion.

Hourly compensation increases in nonfarm business were modest in the second quarter, but the declining CPI-U resulted in the largest quarterly gain in real hourly compensation since 1983. Unit labor costs rose 1.8 percent, reflecting the small rise in productivity and moderate increase in hourly compensation.

Manufacturing. Although discussions of productivity often conjure up images of assembly-line production, manufacturing has long accounted for a small part of all business hours. Manufacturing hours—employment times average weekly hours—have declined from about one-third of business hours in the late 1960's to less than one-fourth presently. Over the same period, manufacturing output has fallen relatively little as a portion of business output—from 29 percent in 1969 to 27 percent in 1986—reflecting the relatively faster rate of productivity growth in manufacturing industries.

During the second quarter of 1986, the productivity advance that occurred in manufacturing resulted mainly from a decrease in hours. Paid hours of all persons engaged in both durable and nondurable goods manufacturing declined. Output was cut back by a smaller amount overall, so productivity rose. This was the first time that both manufacturing output and hours have declined since the recovery began.

Hourly compensation in manufacturing increased at a very modest 2.7-percent annual rate during second-quarter 1986. However, the decline in the CPI-U resulted in an increase in real hourly compensation that was larger than any since 1982. Unit labor costs declined 0.5 percent in the second quarter.

The decline in manufacturing hours was accomplished through cutbacks in both employment and average weekly hours. Employment, which stood at 19.5 million in the second quarter, had grown by about 1.3 million jobs in the first eight quarters of the recovery, but then declined by about 300,000 over the next six quarters.

Nonfinancial corporations. Nonfinancial corporations experienced the third consecutive quarterly decrease in output per hour of all employees during the second quarter of 1986. This was also the first period since the fourth quarter of 1982 during which both output and hours declined. Hourly compensation increased only 1.6 percent, and this is reflected in the moderate 1.9-percent rise in unit labor costs during the period. Unit nonlabor costs—capital consumption allowances, interest, rental income of persons, and indirect business taxes—fell 2.7 percent, and unit profits rose at a 2.0-percent annual rate. The implicit price deflator, which reflects price movements in these costs and profits, rose 0.7 percent in the second quarter, the smallest increase since 1972.

The nonfinancial corporate sector includes all corporations doing business in the United States with the exception of banks, insurance companies, stock and commodities brokers, and finance and credit agencies. About 62 million jobs were provided by these corporations during the second quarter of 1986, 7.7 million more than at the start of the recovery.

Labor input trends. Payroll hours in the business sector have increased at a surprisingly rapid pace during the present recovery. But in manufacturing, growth in paid hours during the last 14 quarters has been slower than during previous long recoveries. This implies that nonmanufacturing firms have experienced very large hours increases during the period. □

—FOOTNOTES—

[1] The BLS labor productivity measures use labor input statistics derived primarily from two monthly BLS surveys, the Current Employment Statistics survey and the Current Population Survey. Output and compensation measures are based on quarterly data prepared by the Bureau of Economic Analysis, U.S. Department of Commerce, as part of the National Income and Product Accounts. For the most recent quarters, the manufacturing output measure reflects movements in the monthly index of industrial production for durable and nondurable manufactures prepared by the Board of Governors of the Federal Reserve System. Further information on the computation of BLS productivity and cost measures can be found in Chapter 13 of the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982).

[2] Business cycles are designated by the National Bureau of Economic Research, a private economic research organization based in Cambridge, MA.

[3] The business sector excludes only those components of gross national product (GNP) for which independent measures of output and labor input are unavailable and components of GNP for which no corresponding labor input measure is available. These are: general government, nonprofit institutions, paid employees of private households, the rental value of owner-occupied housing, the rest-of-the-world sector, and the statistical discrepancy in preparing the National Income and Product Accounts.

The nonfarm business sector is the business sector less farms. The farm sector currently accounts for about 3 percent of business hours.

[4] Hourly compensation measures are divided by the seasonally-adjusted quarterly average of the monthly Consumer Pricer Index for All Urban Consumers.

Sensitivity of BLS economic projections to exogenous variables

The 1995 macroeconomic model has been most responsive to changes in fiscal spending and to changes in foreign economic activity; assumptions regarding energy have had little effect on the estimates

NORMAN C. SAUNDERS

The Bureau of Labor Statistics conducts a comprehensive program of aggregate and industry-level employment projections on a biennial basis.[1] Users of the projections should keep in mind that BLS (or others preparing similar projections) must make many assumptions regarding the behavior of factors which affect the future course of the U.S. economy. In addition, judgments are made about the response of the projections to these primary assumptions. In short, although projections preparation and the use of models in preparing the projections may appear precise and scientific, developing economic projections is very much an art filled with uncertainty.

The assumptions made by BLS cover a broad range, from those about which we may be reasonably certain to those which are not at all predictable. The role of the analyst in preparing projections is to exercise judgment with regard to reasonable expectations for the assumptions, particularly where alternate values may have significant impacts. That is, if a particular assumption is highly uncertain, yet has little impact on the outcome of the projections, it is important that the analysts make that known to the users. Conversely, if the projections are particularly sensitive to specific assumptions, more care must be taken in their preparation.

This article examines the assumptions which affect the aggregate economic projections and illustrates the degree of sensitivity of the projections to possible errors in those assumptions.

Two types of assumptions are required to develop a set of aggregate economic projections. First, values must be assigned to all variables which are exogenous to the aggregate projections model, that is, variables that are not determined by the model but are required to generate a solution. They include such items as real defense expenditures, Social Security benefit payments, and the U.S. currency exchange rate. The second type of assumptions concern the validity of the model structure itself, as these are reflected in changes to that structure in the form of excluded variables, constant adjustments, and modifications to behavioral coefficients.

By their very nature, the first type of assumptions—exogenous variable specification—are the most visible inputs to the model and, also, the most amenable to sensitivity testing. The second type of assumptions are generally less visible, given that they (and their ultimate impact on the projections) are more a function of the projections preparation process. They include explicit assumptions such as expected structural shifts in the economy, the timing of the business cycle, and expectations for productivity growth. This type of assumption is far more difficult to assess for sensitivity purposes.

This article focuses primarily on the sensitivity of the macroeconomic projections (and, to a certain extent, industry-level employment measures) to changes in the aggregate model's exogenous inputs. First, the flow of information into and out of the macroeconomic model is outlined, fol-

---

Norman C. Saunders is an economist in the Office of Economic Growth and Employment Projections, Bureau of Labor Statistics.

lowed by a discussion of the results of the error analysis and an examination of the effects of large, sustained errors in the growth rates of selected exogenous assumptions on the aggregate and industry projections. Finally, the constant adjustments imposed on the model's behavioral relationships are discussed.

The flow of information

The projections process begins with the constrained extrapolation of age-, sex-, and race-specific labor force participation rates.[2] Applying the extrapolated participation rates to the Bureau of the Census projected population levels[3] yields an estimate of the civilian labor force which is used in the aggregate model.

Next, exogenous assumptions are applied to the aggregate model. These assumptions include true policy variables (for example, benefit payments under various Federal transfer programs, the response of the monetary authority to growth in the economy, and the level of the Armed Forces), and variables for which other reliable and generally accepted projections are available, such as the population projections developed by the Bureau of the Census. Exogenous variables also include items which are outside the scope of the model, such as economic growth and inflation rates in the economies of the major trading partners of the United States, the long-term behavior of the U.S. dollar's exchange value, and energy prices.

The aggregate model is then used as a framework for the preparation of the projection of total U.S. economic activity.[4] BLS analysts review the aggregate results for reasonableness, checking for internal consistency and continuity with past trends and comparing the results with projections made by others. Their review focuses on such aggregate measures of economic activity as GNP, unemployment, and productivity, but the model's framework ensures that other important measures of economic performance are not overlooked.

As for industry and occupational projections, the level and distribution of real GNP and employment, as well as several other aggregate variables, are the controlling factors from the aggregate projections model. Following is a summary of major inputs to and outputs from the aggregate projections model:

- Variables incorporated from earlier projection stages
  - Level of the Armed Forces
  - Labor force, age 16 and over, by sex
  - Resident population, all age groups, by sex
- Variables incorporated as part of the macroeconomic stage of the projections
  - Fiscal policy assumptions
  - Monetary policy assumptions
  - Foreign economic activity assumptions
  - Energy price and availability assumptions
- Variables passed from the macroeconomic model to later stages of the projections
  - Gross National Product
    - Personal Consumption Expenditures
    - Gross Private Domestic Investment
    - Exports
    - Imports
    - Government
  - Employment
  - Miscellaneous

The flow of information in the early stages of projection development is from the more aggregate to the more detailed. In the later stages, a less formal, but no less important, feedback occurs from the industry and occupational projections to the more aggregate level. Because of the review and feedback process, BLS projections converge to an internally consistent set of solutions at all levels of the estimation process.

Error analysis

The macroeconomic model used by BLS requires the values for 849 exogenous variables to generate a solution. Following is a breakdown by type of all variables and of the subset of those variables included in the subsequent analysis:

	Total	*Included in analysis*
Total	849	373
Fiscal	29	26
Income	40	40
Financial	18	18
Tax-related	161	146
Foreign activity	11	11
Demand-related	37	37
Energy	136	36
Technical input/output	170	0
Demographic	46	46
Miscellaneous	13	13
Model switches	188	0

Variables were excluded from consideration if they controlled program flow (model switches), accounted for extraordinary variability in historical data series (dummy variables), or were of a highly detailed industry-specific nature. A separate run of the model was performed for each of the 373 exogenous variables used.

The assumption was made that the underlying trend of each variable was correct for the 1985–95 period, but that the initial period estimate was in error by 10 percent. Thus, the exogenous value was increased by 10 percent in each year of the period, a model solution was generated, and the results were compared with the results of the base projection. Comparisons were made of those variables which are used at later stages of the projections—GNP and major demand components, employment, the unemployment rate,

Table 1. Difference between selected exogeneous variables used to generate 1995 projections values as published and as generated by a 10-percent error
[In percent]

Exogenous variable	GNP, 1972 dollars	GNP, current dollars	Employment	Unemployment rate	Large time deposit rate
Fiscal:

Demographic:					
Male labor force, age 16 and over	.9	1.1	1.2	3.8	–
Female labor force, age 16 and over	.7	.9	.9	3.2	–
Tax-related:					
Ratio, personal income of States with an income tax to total income	−.5	−.7	−.7	.6	−.1
Value of a standard deduction, average	.2	.3	.3	−.3	–
Value of an individual exemption	.2	.2	.2	−.2	–
Maximum taxable salary, OASDHI	−.1	–	−.1	.1	–
Indirect business tax rate	−.3	1.2	−.3	.2	−.1
Effective corporate tax rate	−.3	−.3	−.3	.2	−.2
Effective State personal income tax rate	−.5	−.7	−.7	.6	−.1
Combined OASDHI tax rate	−1.0	.1	−1.2	1.2	−.2
Personal tax alternatives:					
No indexation of rates (versus full indexing)	−8.8	−4.0	−3.5	3.3	−2.4
10-percent tax cut (across the board)	1.9	2.4	2.3	−2.1	.4
10-percent tax increase (across the board)	−1.7	−2.2	−2.2	2.0	−.1

GNP per labor hour, the inflation rate (as measured by the rate of change in the implicit price deflator for GNP), and the interest rate on large time deposits (the key interest rate in the macroeconomic model).

Table 1 shows the percent difference between the published moderate-growth projection values and those generated by the alternative solution. Also included is the absolute difference in the unemployment rate between the two model solutions and the impact on the interest rate on large time deposits. Exogenous variables having insignificant impacts on these specific variables were not included in the table.

The macroeconomic model appears to be most sensitive to changes in fiscal policy assumptions, both revenues and expenditures, and to assumptions concerning foreign economic activity. Changes in assumptions regarding the energy sector, especially the barrel price of imported crude petroleum, have very little impact on the macroeconomic estimates passed along to later stages of the projections process.

To better analyze the effects of fiscal expenditure shifts on projections, the immediate and long-term multipliers for selected Federal and State and local government expenditure categories are shown in the following tabulation:

	Immediate effect	*11-year effect*
Federal:		
Defense spending	1.83	2.36
Nondefense spending	1.94	2.51
Military retirement	.71	1.83
Medicare benefits	1.56	1.97
Social Security benefits	.73	1.81
Other Federal transfers	.72	1.77
State and local:		
Education purchases	1.82	1.95
Health and welfare purchases	1.72	1.91
Civilian safety purchases	1.78	1.90
Other State and local purchases	1.76	1.89
Transfer payments	.72	1.53

Table 2 presents the absolute differences in the percent shares of GNP accounted for by the major demand components of GNP. As with the level of GNP and employment, the significant impacts appear to be related primarily to fiscal policy and foreign economic activity assumption changes.

The macroeconomic model includes two types of monetary policy assumptions. The first includes many of the small components of the various definitions of the money supply. These assumptions affect only the determination of M1 (the narrow definition of the money supply) and M3 (the broadest definition of the money supply) and have no impact whatsoever on other sectors of the model.

The second type of monetary policy assumption is the "decision rule" used by the Federal Reserve Board to determine the optimal rate of growth of M2. In the macroeconomic model used by BLS, the decision rule is formulated as the willingness of the monetary authority to accommodate current levels of inflation and real growth in the current period. Choices range from fully accommodative (easy money) to the least accommodative (tight money).

Accommodation policies affect real and nominal GNP growth, employment and inflation growth, the interest rate on large time deposits, and the unemployment rate. The impacts are quite small, which is not particularly surprising in a model of this type. Monetary control, by its very nature, is a short-term phenomenon which depends on the dynamics of a detailed financial sector specification normally found only in the many short-term forecasting models available for the U.S. economy. Long-run determinants of potential

Table 2. Difference between the distribution of GNP in the 1995 projections values as published and as generated by alternate assumptions for exogenous variables

[In percent]

Exogenous variable	Personal Consumption Expenditures (PCE)			Investment			Foreign trade		Government

Corporate tax rate	-.04	–	.03	-.10	.01	–	.03	.02	.02	.05
State tax rate	-.10	-.07	-.01	-.02	–	–	.06	.04	.04	.06
Combined OASDHI rate	-.16	-.07	.05	-.06	.04	.01	.04	-.02	.08	.11

growth are generally understood to be more related to those factors which affect the trend path of demand growth, such as demographic factors and patterns in income growth. Thus, the monetary policy instruments, while useful in influencing the short-run behavior of the macroeconomic model, generally do not affect projections which focus on long-term growth.

Growth-rate shift analysis

The error analysis tests for the relative sensitivity of the macroeconomic model to sustained level shifts or errors in a specific exogenous variable. Some of the key asumptions, however, are subject to wide, relatively unpredictable fluctuations. To test the sensitivity of the model and projection results to unexpected fluctuations in the growth rates of selected exogenous variables, six exogenous variables were selected and two solutions were prepared for each, as follows:

- Defense purchases of goods and services (1972 dollars):
  - Variable unchanged, 1985–95 (no real growth).
  - Annual real growth of 5 percent.
- Federal nondefense purchases of goods and services (1972 dollars):
  - Variable unchanged, 1985–95 (no real growth).
  - Annual real growth of 5 percent.
- Federal transfer payments, Social Security benefits (1972 dollars):
  - Real average annual decline of 5 percent.
  - Real average annual increase of 5 percent.
- Gross domestic product, our major trading partners (1972 dollars):
  - Annual real growth of 1 percent.
  - Annual real growth of 5 percent.
- Average exchange rate index, our major trading partners:
  - No change, 1985–95 (value of the dollar remains constant over the period).
  - Annual growth of 8 percent (value of the dollar falls smoothly over the entire period).
- Price of imported crude petroleum:
  - Price declines to $18 per barrel by 1988 and remains at that level thereafter.
  - Price declines to $26 per barrel in 1986 then begins to increase again, reaching $60 per barrel by 1995.

Table 3 shows the percent difference for each of the six exogenous variables and the associated impact on the major results of the aggregate model solutions.

The major demand components, for each of the 12 aggregate solutions, were allocated by producing sectors using the distributions implicit in the published BLS base projections. The resulting final demand bills of goods were applied to the 1995 input-output table from the same published projections to arrive at detailed estimates of industry total output necessary to produce the aggregate GNP. Finally, the industry output estimates were translated to employment requirements using the employment/output ratios from the published base projections. The resulting percent changes in employment between the two alternative solutions for each of the selected exogenous variables are presented, at the sector level, in table 3.

The implications are that, at least for the selected variables, large errors in specification could lead to significantly altered results, at both the aggregate and industry levels of detail. In subsequent projections preparation, it would be worthwhile to develop such "single-variable" alternatives.

Add-factor analysis

For each behavioral relationship in the macroeconomic model, the analyst may specify adjustments to the constant term of the equation. These are called add-factors because they displace the result of the equation up or down by an additive amount. Constant adjustments may be applied in one or more years of the solution interval, may be constant, declining, or increasing over time, and, in short, allow for tremendous control by the analyst over the solution path and results of the model.

Normally, constant adjustments are initially specified for virtually every behavioral equation in a complex model to smooth the vagaries of individual equations and to force the model to reproduce the last few years of available historical data. These add-factors would then be tapered smoothly to a zero value at some point in the solution interval. Indeed, without this initial step, large economic models will generally be unable to converge on a solution at all.

Finally, to derive an acceptable solution, the analyst introduces modifications to exogenous values and further changes to the constant adjustment factors. In some cases, where the dynamics of the model make the effects of changes to constant adjustments unpredictable, the analyst may elect to exclude certain behavioral relationships. That is, the equation is "turned off" and exogenously specified values are supplied in place of the equation results. Once an acceptable solution has been derived, all of the add-factors are recomputed so that previously excluded variables may be included again in the solution set.

From the foregoing discussion, it is clear that an econometric model provides a convenient framework for a set of economic projections. However, the way that framework is fleshed out is, to a great extent, a reflection of the experiential judgments of the analysts preparing the projection. In fact, it has been estimated that as much as 70 percent of the content of a particular projection set is attributable to the judgments of the analyst and the remaining 30 percent to the formal structure of the econometric model.

The BLS 1995 projections process was begun with the Wharton control forecast of June 1984 as the starting point. Thus, the preliminary step of calibrating the constant adjustments had already been performed. However, to derive a reasonable trend projection of growth, BLS had to replace the Wharton exogenous variables with its own estimates, and, more importantly, to disentangle the Wharton constant adjustments which had been overlaid on the calibrating adjustments. One of the primary features of the Wharton forecast was that it contained a strong cyclical component, and many of the initial changes to the Wharton add-factors were necessitated by BLS' goal of a cycle-free trend projection.

A comparison of the Wharton constant adjustments was made with those of BLS for 106 behavioral relations in the model: 71 demand categories (all behaviorally determined components of real GNP), 33 employment levels (all behaviorally determined sectoral employment), and the male and female civilian labor force. Following is the number of behavioral relations where the constant adjustment as a proportion of the determined variable increased or decreased over time:

Equation	*Increased*	*Decreased*
Demand:		
BLS	37	34
Wharton	35	36
Employment:		
BLS	18	15
Wharton	10	23
Labor force:		
BLS	2	0
Wharton	2	0

The relation of the BLS constant adjustment to that in the Wharton control is shown below:

Equation	*Larger*	*Smaller*	*Identical*
Demand	39	21	11
Employment	24	4	5
Labor force	0	2	0

Exactly how one should interpret these comparisons is moot. Generally, the BLS add-factors are larger than those of Wharton. This may reflect a greater propensity on the part of BLS analysts to experiment with the structure of the model, or it may reflect the smoothing that BLS imposed on the macroeconomic results.

Recall that the BLS macroeconomic projections do not stand completely on their own merits. Where detailed results at lower levels of the projection process contradict the aggregate results, the aggregate projections are often modified to take into account these contradictions. This factor alone accounts for BLS' apparent tendency to more heavily add-factor the employment equations than does Wharton.

Conclusions and recommendations

The key results of the macroeconomic model are more heavily influenced by some exogenous assumptions than by others. These include Federal spending and tax policy and the assumptions relating to foreign economic activity. Perhaps far more important, but much less straightforward to quantify, are the impacts of model structure modifications, in the form of constant adjustments, on projection results.

Table 3. Effects of large changes in selected exogenous variables on major projected variables and sectoral employment as compared to those published for 1995
[In percent]

Item	Defense purchases	Nondefense purchases	Social Security benefits	Foreign gross domestic product	Exchange rate	Import oil price
Major projected variable						
Exogenous variable difference	62.9	62.9	172.1	37.8	115.9	233.3
Real GNP	6.5	2.3	5.3	5.4	12.6	-.7

Maintenance and repair construction	5.6	1.4	3.5	3.1	8.2	-.4
Manufacturing	9.7	2.1	6.2	9.5	25.7	-.8
Transportation	7.7	1.9	6.4	7.0	15.7	-.8
Communications	5.7	1.8	6.5	5.1	11.0	-.5
Public utilities	6.8	2.2	8.6	4.8	13.6	-.1
Wholesale and retail trade	6.4	2.2	8.7	4.6	7.7	-.7
Finance, insurance, and real estate	3.8	1.5	6.0	2.8	7.1	-.3
Other services	5.1	2.1	6.0	3.2	7.8	-.3
Government enterprises	5.7	1.7	6.7	4.1	9.7	-.8
Special industries	3.9	1.8	5.2	2.5	5.9	-.8

BLS' current methodology is to prepare a base projection and several alternative projections. The purpose of the alternative projections has been primarily to put confidence intervals around the base projection. This approach should continue, with special focus on those variables most heavily add-factored in the preparation of the base projection.

What BLS methodology has been lacking, however, is the identification and exploration of alternatives around those exogenous assumptions which most heavily impact the key macroeconomic results. Therefore, in addition to the alternative projections mentioned above, the foregoing results should be used to identify those specific exogenous assumptions for which alternative scenarios should be developed. Such "single-variable" alternatives would be relatively inexpensive to generate (relative to "whole-model" alternatives) and would add greatly to the usefulness of the BLS projections, in that they would assist users in identifying results which are most likely to be affected by unexpected developments in key assumptions. □

Research Summaries

Women veterans total 1 million in first half of 1986

MARIA L. ROCA

A large portion of our male population has served in the Armed Forces of the United States, and there has long been a demand for information on their post-service adjustment to the civilian labor market. Data on male veterans of World War II, for example, were published regularly by BLS in the 1940's and 1950's,[1] and population and labor force data on those who served during the Vietnam era have been published monthly since 1971. By contrast, women did not begin to serve in the Armed Forces to a significant degree until the mid-1970's. With this rise in service participation, there has been an increase in the number of women joining the veteran ranks. Beginning in January 1986, data on female veterans first became available from the Current Population Survey (CPS). This report discusses the current role of women in the military services and provides a summary of the new CPS data.

Women in the military. Women began active participation in the military during the early part of this century, with the establishment of the Army Nurse Corps in 1901 and the Navy Nurse Corps 7 years later. But, while they were recognized as military personnel, these women were denied equal rank, comparable pay, and veteran status.[2] It was not until the second half of the century that they began to be recruited in large numbers for a wider range of jobs providing equal pay and full veterans' benefits.

Women in the military today find a broad range of job opportunities available to them. Though many continue to serve in such traditional specialties as health and administration, others work in such diverse fields as sonar and aircraft equipment repair, radio and air traffic control, law enforcement, and meteorology. While each service has its own regulations, the only occupational restrictions women generally encounter in the military are those associated with direct combat, and so very few serve in the infantry, on gun crews, and on combat ships.[3]

In March 1986, the Department of Defense reported that there were 215,000 women in the military, comprising approximately 10 percent of the total Armed Forces. In the post-Vietnam era (since 1975), the number of enlisted women has increased by 100,150 and the number of female officers by 17,200—or by 120 and 126 percent, respectively.[4] Over this same period, the size of the total Armed Forces has changed little.

The new data. Given the small sample of female veterans in the CPS, the new data allow for little analysis of such issues as post-service employment and unemployment experience. Nevertheless, the accompanying tables provide limited labor force and population data for the average of the first 6 months of 1986; 6-month averages were used because they are somewhat more reliable than data for an individual month.

During the first half of 1986, the female veteran population averaged 1,030,000. (See table 1.) About 55 percent of these women participated in the labor force, the same proportion as for female nonveterans. The majority of female veterans served during a designated wartime period: almost 250,000 were Vietnam-era veterans, 70 percent of whom were between the ages of 30 and 39. (See table 2.) The labor force participation rate for these veterans, almost 80 percent, was higher than that of any age group of female nonveterans. The unemployed among this group averaged only 9,000 persons, yielding a jobless rate of about 5 percent. However, the sample on which such estimates are based is so small that any interpretation of these data is problematic.

About 450,000 women were veterans of other wars. These women were primarily involved in World War II and the Korean conflict and thus were mainly between the ages of 60 and 69. Because of this concentration in the older age

Table 1. Labor force status of women 18 years and over by veteran status, January–June 1986 averages

[Numbers in thousands]

Veteran status	Civilian noninstitutional population	Civilian labor force	Labor force participation rate
Total veterans	1,027	562	54.7
Vietnam-era veterans	245	193	78.8
Other war veterans	452	135	29.9
Peacetime veterans	330	234	71.0
Nonveterans	93,504	51,244	54.8

Table 2. Age distribution of the female population 18 years and over by veteran status, January-June 1986 averages

Age	Veterans			Non-veterans
	Vietnam-era veterans	Other war veterans	Peace-time veterans	
Total (in thousands)	245	452	330	93,504
Total (in percent)	100.0	100.0	100.0	100.0
18 to 29 years	4.5	—	52.7	26.2
30 to 39 years	69.7	—	22.1	20.7
40 to 49 years	20.0	0.9	16.4	14.1
50 to 59 years	3.3	20.4	5.2	12.2
60 to 69 years	1.2	63.1	1.2	11.5
70 years and over	1.2	15.9	2.4	11.5

groups, the labor force participation rate for "other" war veterans is relatively low, about 30 percent.

The last group identified through the survey was peacetime veterans, generally those who served between World War II and the Korean conflict, between the Korean conflict and Vietnam, and during the post-Vietnam era. In early 1986, there were 330,000 peacetime veterans, 71 percent of whom were labor force participants.

The Bureau of Labor Statistics will make the data on female veterans available upon request. ☐

Military and civilian wives: update on the labor force gap

HOWARD V. HAYGHE

In an era when wives' earnings are a major component of family income, many military wives experience labor market difficulties which can have a serious impact on the economic well-being of their families. This, in turn, can affect the ability of today's all-volunteer Armed Forces to retain the highly skilled, experienced personnel that are vital to its mission.

This report updates a 1981 *Monthly Labor Review* article comparing the labor force patterns of military and civilian wives.[1] The recent situation is described first and is followed by a review of trends since 1970.

Status in March 1986

About 846,000 women in the United States were living on or off military posts with husbands who were members of the Armed Forces in March 1986. An additional 50,000 women were separated from their spouses because the men had been assigned to ships, overseas duty, or other posts where the family could not accompany them.[2]

Of the women living with their husbands 52 percent were working or looking for work, compared with 55 percent of civilian wives. However, this similarity is misleading. When the age difference between military and civilian wives is taken into account, military wives are substantially less likely to be in the labor force.

The age distribution of military wives can be estimated from that of their husbands. We know that, in general, women tend to marry men who are about 2 to 3 years older than themselves. In 1986, for example, the median age for married women, husband present, was 42.1 years, compared with a median of 44.8 years for husbands. As shown in the percent distribution below, husbands in military services are a great deal younger than their civilian counterparts.

Age	*Military husbands*	*Civilian husbands*	*All wives*
Total	100	100	100
16 to 19	2	–	–
20 to 24	17	4	7
25 to 34	49	23	26
35 to 44	26	23	23
45 and over	6	50	44

Thus, it can be expected that as a group, military wives are also considerably younger than all civilian wives. Indeed, virtually all are probably under 45 years of age. For the sake of consistency, labor force comparisons for military wives will be made with all wives 16 to 44 years old. (The proportion of military wives is only about 2.9 percent of all married women these ages, so their effect on labor force data pertaining to all 16- to 44-year-old wives is clearly negligible. Thus, all wives in the age group can be considered as the civilian counterparts of military wives.)

Overall, the labor force participation rate of military wives (52 percent) was nearly 15 percentage points lower than that of their civilian counterparts. Moreover, whatever their race or motherhood status, military wives were less likely than the 16- to 44-year-olds to be labor force participants. (See table 1.) For instance, white military wives had a participation rate in 1986 that was 18 percentage points lower than the rate for their civilian counterparts. Among blacks, the difference was about 11 percentage points. The presence of preschool children appeared to limit military wives' labor force activity more sharply than that of the

Table 1. Population and labor force participation rates of military and civilian wives by race and presence and age of children, March 1986
[Numbers in thousands]

Characteristic	Military wives, 16 years and older	Civilian wives, 16 years and older	All wives, 16 to 44 years old
Population			
Total	846	50,132	29,228
White	669	45,285	25,967
Black	138	3,570	2,213
With no children under age 18	221	26,100	7,079
With children under age 18	625	24,032	22,150
Children ages 6 to 17 only	216	12,499	10,027
Children under age 6	409	11,533	12,123
Labor force participation rate[1]			
Total	52.1	54.6	66.9
White	48.1	53.6	66.1
Black	65.9	64.3	77.1
With no children under age 18	68.3	48.0	82.6
With children under age 18	46.4	61.8	61.8
Children ages 6 to 17 only	66.2	68.5	71.4
Children under age 6	35.7	54.5	53.9

[1] Labor force as a percent of population.

NOTE: Because of rounding, sums of individual cells may not equal totals.

other group of wives with children that age, but the difference narrowed for those with school-age children. However, even when there were no children in the family, the military wives' participation rate was lower.

Unemployment rates were higher across the board for military wives than for the other wives—10.7 versus 6.0 percent. This is partly a function of the black-white mix as well as greater family mobility; black wives constituted 16 percent of the total, versus 8 percent of all civilian wives.

When employed, military wives are more concentrated in sales and service occupations than civilian wives. About 35 percent of military wives held such jobs in March 1986, compared with 27 percent of civilian wives. At the same time, military wives were less likely to be in professional specialty jobs—12 versus 16 percent. Service and sales jobs frequently offer the flexibility of part-time employment, do not necessarily require specialized training, and are often typified by high employee turnover. Hence, even though they are characterized by low earnings,[3] they are probably easier for military wives to obtain than other jobs, for which longer-term commitments are often expected.

Trends

The relatively low labor force participation rates of military wives are not a new development. In 1970, shortly after the Bureau of Labor Statistics first tabulated data for this group, 31 percent of military wives were working or looking for work. In contrast, 44 percent of their civilian counterparts were in the labor force. Since then, the rates for both groups have increased by a little more than 20 percentage points. Thus, by 1986, the rates were 52 percent for military wives and 67 percent for the other wives—practically the same difference as in 1970.

While the participation rates for civilian wives advanced steadily over the period, the trend for military wives was erratic. In addition to the demographic, economic, and social factors that influence the labor force activity of both civilian and military wives,[4] the rates for military wives are also likely to be affected by changes in the flows of enlistments, transfers, and discharges of their husbands. This may also partly account for the erratic movements in military wives' unemployment rates.

Table 2. Labor force and unemployment rates of military and civilian wives, March 1970 to March 1986

Year	Labor force participation rate[1]			Unemployment rate[2]		
	Military wives, 16 years and older	Civilian wives, 16 years and older	All wives, 16 to 44 years old	Military wives, 16 years and older	Civilian wives, 16 years and older	All wives, 16 to 44 years old
1970	30.5	41.2	43.7	13.0	4.5	5.7
1971	27.2	41.1	44.0	10.4	5.7	7.3
1972	26.8	41.9	45.3	10.0	5.2	6.4
1973	33.3	42.5	47.5	13.1	4.4	5.3
1974	36.3	43.3	48.9	12.4	4.5	5.8
1975	39.3	44.6	51.1	16.3	8.3	10.0
1976	38.0	45.3	52.1	12.7	7.0	8.4
1977	38.2	46.8	54.7	18.0	6.6	7.8
1978	46.6	47.7	56.3	16.5	4.9	6.2
1979	50.2	49.4	58.7	11.8	4.9	5.9
1980	50.6	50.2	60.3	10.9	5.1	6.2
1981	50.7	51.1	61.6	8.0	5.6	6.8
1982	51.9	51.3	62.4	13.5	6.9	8.1
1983	47.5	51.9	63.4	17.2	6.9	8.2
1984	50.6	53.0	64.5	16.9	5.4	6.7
1985	52.1	54.4	66.3	17.8	5.5	6.3
1986	52.1	54.6	66.9	10.7	5.2	6.0

[1] Labor force as percent of population.

[2] Unemployed as percent of labor force.

NOTE: Data are not seasonally adjusted.

Clearly, military wives have made considerable progress in the labor market. But a number of articles and studies indicate that frequent transfers of their husbands place many military wives at a labor market disadvantage. It has long been known that high mobility means frequent breaks in the wife's employment or education and training.[5] One result is that her opportunities to develop a marketable career are disrupted; another is that she must search for jobs in unfamiliar geographic areas. Moreover, the concomitant lack of experience, training, and seniority may result in lower earnings for military wives.[6] They may also experience some job discrimination because of the likelihood that they will not remain with an employer for very long.[7] But, whatever the cause, or causes, of military wives' labor market problems, these problems continue to be a source of concern not only to the families themselves, but also to the Armed Services as a whole. ☐

Occupational pay in textile dyeing and finishing plants

Production and related workers in the textile dyeing and finishing industry averaged $6.67 an hour in June 1985, according to a study by the Bureau of Labor Statistics.[1] Regionally, average hourly earnings were highest in New England ($7.67) and lowest in the Southeast ($6.42), where three-fourths of the 36,300 production workers were employed. The Middle Atlantic States, employing one-tenth of the workers, recorded $7.27 an hour. (See table 1.)

Wages in mills processing textiles for their own account averaged virtually the same as mills processing materials for customers on a commission basis (textiles owned by others), $6.67 and $6.68, respectively. Employment was equally divided between these two types of finishers.

Pay in mills primarily processing manmade textiles—seven-tenths of the work force—averaged $6.83 an hour, 6 percent more than the $6.42 recorded among cotton textile processors. Within both of these groups, pay nearly always averaged more per hour in fabric mills than in yarn or thread mills.

Pay levels also were compared by type of area, size of establishment, and labor-management contract coverage. Average hourly earnings were 11 percent higher in metropolitan areas[2] than in nonmetropolitan areas ($7.10 versus $6.39). Pay in plants with at least 500 employees averaged $6.84 an hour, the same as in plants with 250 to 499 employees, but was higher than in plants with 50–249 employees ($6.45 an hour). In establishments where a majority of the workers were covered by labor-management agreements, pay averaged $7.57 an hour, 19 percent more than the $6.35 in nonunion establishments. Regionally, the pay advantage for production workers in union establishments was 5 percent in the Southeast, 15 percent in New England, and 48 percent in the Middle Atlantic region.

Forty occupations, accounting for nearly three-fifths of the production workers, were selected to represent the industry's wage structure, workers' skills and manufacturing operations. Pay levels among these jobs ranged from $5.63 and hour for janitors, porters, and cleaners, to $9.71 for machine printers. Tenders of cloth-dyeing machines, numerically the largest job studied separately, averaged $6.92 an hour. Occupational pay levels varied by pay determining characteristics such as region, type of textile processed, size of establishment, and union contract status; the interrelationships among these factors, however, were not taken into account when tabulating the data.

Virtually all production workers were in establishments providing paid holidays, paid vacations, and at least part of the cost of various health and insurance plans. Seven to 10 holidays annually were typical, as were 1 to 4 weeks of vacation pay, depending on years of service.

Retirement pension plans (in addition to Social Security) covered approximately three-fourths of the work force, while retirement severance plans applied to nearly one-tenth. Employers typically paid the entire cost of these retirement plans.

One-fourth of the workers were employed in establishments having collective bargaining agreements covering a majority of the production workers. Regionally, the proportions were one-tenth in the Southeast, seven-tenths in the

Table 1. Average hourly earnings[1] in textile dyeing and finishing plants, United States and selected regions,[2] June 1985

Characteristic	United States[3]	New England	Middle Atlantic	Southeast
All production workers	$6.67	$7.67	$7.27	$ 6.42
Type of finisher:				
Commission mill	6.66	7.58	7.54	6.00
For own account	6.67	8.03	5.31	6.65
Type of textile:				
Cotton[3]	6.42	7.71	6.35	6.18

[1] Excludes premium pay for overtime and for work on weekends, holidays, and late shifts. Incentive payments, such as those resulting from piecework or production bonus systems, and cost-of-living pay increases (but not bonuses) were included as part of the workers' regular pay. Excluded are performance bonuses and lump-sum payments of the type negotiated in the auto and aerospace industries, as well as profit-sharing payments, attendance bonuses, Christmas or yearend bonuses, and other nonproduction bonuses.

[2] The regions used in this study include: *New England*—Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont; *Middle Atlantic*—New Jersey, New York, and Pennsylvania; and *Southeast*—Alabama, Florida, Georgia, Mississippi, North Carolina, South Carolina, Tennessee, and Virginia.

[3] Includes data for subclassifications in addition to those shown separately.

[4] Metropolitan Statistical Areas as defined by the U.S. Office of Management and Budget through June 1983.

NOTE: Dashes indicate no data were reported or that data did not meet publication criteria.

Middle Atlantic, and four-fifths in New England. The major union in the industry was the Amalgamated Clothing and Textile Workers Union (AFL-CIO).

A comprehensive bulletin on the study, *Industry Wage Survey: Textile Dyeing and Finishing, June 1985*, BLS Bulletin 2260, may be purchased from the Bureau of Labor Statistics Publication Sales Center, P.O. Box 2145, Chicago, IL 60690, or the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402. The bulletin provides additional information on occupational pay and on the incidence of employee benefits. The study covered 223 establishments primarily engaged in dyeing and finishing nonwool yarn, thread, cloth, or other textile products and employing 50 workers or more. ☐

FOOTNOTES

[1] Wage data are straight-time earnings which exclude premium pay for overtime and for work on weekends, holidays, and late shifts. Incentive payments, such as those resulting from piecework or production bonus systems, and cost-of-living pay increases (but not bonuses) were included as part of the workers' regular pay. Excluded are performance bonuses and lump-sum payments of the type negotiated in the auto and aerospace industries, as well as profit-sharing payments, attendance bonuses, Christmas or yearend bonuses, and other nonproduction bonuses.

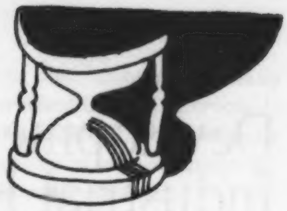
Major Agreements Expiring Next Month



This list of selected collective bargaining agreements expiring in January is based on information collected by the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more. Private industry is arranged in order of Standard Industrial Classification.

Industry or activity	Employer and location	Labor organization[1]	Number of workers
Private			
Construction	National Electrical Contractors Association, Northwest Line Constructors (Interstate)	Electrical Workers (IBEW)	1,200
	Associated General Contractors, Cincinnati Division Ohio Building Chapter and one other (Ohio)	Carpenters	2,800
Food products	Wholesale, retail bread and cake bakeries (New York, NY)	Bakery, Confectionery and Tobacco Workers	3,000
	Chef Boy-Ar-Dee, division of American Home Foods (Milton, PA)	Food and Commercial Workers	1,350
	Bryan Foods Inc. (West Point, MS)	Food and Commercial Workers	1,200
	Del Monte Corp., Midwest Division (Illinois)	Retail, Wholesale and Department Store	1,200
Textiles	Erwin Mills (Erwin, NC)	Clothing and Textile Workers	1,150
Stone, clay, and glass products	Corning Glass Works (Corning, NY)	Flint Glass Workers	3,500
Primary metals	Blaw Knox Foundry & Mill Machinery, Inc. (Interstate)	Steelworkers	1,500
Electrical products	Litton Industries, Inc. (Sioux Falls, SD)	Electrical Workers (UE-Ind.)	2,100
Transportation equipment	United Technologies Corp. (West Palm Beach, FL)	Machinists	1,300
	Dana Corp., Spicer Axle Division (Ft. Wayne, IN)	Industrial Workers	1,650
Air transportation	Western Airlines, flight attendants (Interstate)	Flight Attendants	2,300
	Western Airlines, clerks and agents (Interstate)	Air Transport Employees	4,500
	Western Airlines, ground service (Interstate)	Teamsters (Ind.)	1,600
Communication	General Telephone Co. of Wisconsin (Wisconsin)	Communications Workers	1,250
Utilities	Boston Gas Co. (Boston, MA)	Steelworkers	1,000
	Utah Power & Light Co. (Interstate)	Electrical Workers (IBEW)	3,800
Wholesale trade	Associated Produce Dealers & Brokers of Los Angeles (California)	Teamsters (Ind.)	1,900
Retail trade	Acme Markets, Inc. (Philadelphia, PA)	Food and Commercial Workers	5,000
	Acme Markets, Inc. (New Jersey)	Food and Commercial Workers	2,700
	Acme Markets, Inc. (Delaware)	Food and Commercial Workers	1,250
Real estate	Midtown Realty Owners Association, Inc.	Service Employees	2,500
Public			
Education	Michigan: Detroit Board of Education, office	Educational Office Employees	1,800
	Detroit Board of Education, maintenance, custodial, transportation	State, County and Municipal Employees	2,400
	Detroit Board of Education, paraprofessional	Detroit Association of Educational Employees	1,400

Developments in Industrial Relations

Health insurance extended to the unemployed

Employees and their dependents gained additional health insurance protection in 1986 under provisions of the Consolidated Omnibus Budget Reconciliation Act of 1985 (Public Law 99–272). Under the Act, employers with more than 20 employees who offer group health insurance must continue coverage for up to 18 months for workers who are laid off or quit, and for up to 36 months for widows and divorced spouses and their dependents. Employers generally criticized the provisions, even though the cost of the mandated coverage, and a 2-percent administration fee, must be borne by the beneficiaries.

The employers contend that it will be difficult and expensive to keep track of former employees, particularly in high turnover industries. They also maintain that premiums will be driven up because persons with chronic medical problems will tend to retain coverage. Another problem, according to critics, is that some people will not continue coverage, but will initiate coverage if they suffer a health problem. The law provides for retroactive coverage if the employer receives the first premium within 105 days after an applicant indicates he or she intends to join the plan.

Proponents of the coverage extension say it is vital to help reduce the number of people not protected by health insurance, estimated to be between 30 and 37 million.

NLRB upholds safety complaint ruling

In a 3–0 decision, the National Labor Relations Board affirmed its 1984 ruling that an employer was justified in firing an employee who acted alone in refusing to drive a company truck he deemed unsafe. In its 1986 opinion, the Board said the employee's action would have been warranted if it was "concerted" or "engaged in with or on the authority of other employees, and not solely by and on behalf of the employee himself."

In the 1984 decision, the Board had reversed the precedent it had established in a 1975 case in which it had expanded the definition of "concerted activity" by ordering the reinstatement of a maintenance worker who was fired after he acted alone in filing a safety complaint with a State agency. On appeal, a Federal district court had reversed the 1984 decision and returned it to the Board for reconsideration. In its finding, the district court said that the Board had "misconstrued the bounds of the law," which is intended to protect workers who act to protect themselves on the job.

The attorney for Kenneth Prill, the fired truck driver, said the Board's 1986 decision would be appealed. The employer involved is Meyers Industries, a boat manufacturer located in Tecumseh, MI.

Boston University faculty cannot bargain

The National Labor Relations Board upheld a hearing examiner's finding that department heads and full-time faculty at Boston University are managerial employees and therefore not entitled to bargain collectively. In its 4–0 ruling, the Board said "the faculty has absolute authority over such matters as grading, teaching methods, graduation requirements and student discipline." The Board also said that the teachers also play "an effective and determinative role" in recommending faculty hiring, tenure, promotions, and reappointments. The ruling was based on a 1980 Supreme Court decision that full-time faculty members at Yeshiva University were not covered by the National Labor Relations Act because they had managerial duties.

Ann Franke, associate counsel of the American Association of University Professors, called the decision "another precedent that administrations will find extremely useful in justifying a refusal to bargain." She said the Association was considering an appeal of the decision and that future rulings in such cases will hinge on the extent of faculty involvement in school management. The decision does not prohibit faculty members from joining unions or associations such as the American Association of University Professors, which has had a chapter at Boston University since 1975.

Catfish processors vote for union representation

The Food and Commercial Workers claimed a major victory in its 7-year organizing campaign in Mississippi after winning a representation election at Delta Catfish Processors' plant in Indianola. About 925 of the company's 1,050 employees were eligible to vote in the National Labor Relations Board election. The tally was 489–349 in favor of the union. More than 2,000 workers in the State are employed in the catfish processing industry, of which Delta is the largest employer.

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

At the time of the election, the union was negotiating with Farm Fresh Catfish in Hollandale on an initial contract for 200 workers it organized in 1985.

The organizing drive, which has also included other types of industries in the State, has also encountered some setbacks. The latest came in August, when workers at ConAgra's catfish plant in Isola rejected union representation by a 162-to-119 vote.

During the representation drive at Delta Catfish, the Food and Commercial Workers contended that the employees were underpaid, averaging $3.90 an hour, did not have paid sick leave or adequate health insurance, and were subject to excessive discipline. The company maintained that the employees did not "need a third party to speak for them because our company and our employees will work out any problems we might have."

Winery workers accept previously rejected pact

A 7-week strike against 11 of California's largest wineries ended when the employers threatened to hire permanent replacements for the 2,200 striking workers. The strike occurred during the critical grape-crushing season, but the wineries maintained normal production using supervisory employees, temporary replacements, and some returning strikers, according to an official of the California Winery Employers Association.

George J. Orlando, President of the Distillery, Wine and Allied Workers union, said that employee acceptance of the "final offer" they had turned down 5 days earlier resulted from "the understandable fear that remaining on the picket line would result in the loss of their jobs."

The settlement provided for an immediate cut of 50 cents an hour in pay, which ranged from $6.34 to $15.54 according to the Association, and averaged $10.75 according to the union. There also was a 25-cent-an-hour cut in the employers' financing of pensions, and an increase in the annual individual deductible under the health insurance plan.

In another important change, the agreement will run to March 31, 1991, diminishing the impact of a possible strike because it will occur prior to the grape-crushing period. The previous contract expired on July 31, 1986.

The Association said the compensation cuts accepted by the employees were needed to help the wineries compete with increased imports and with a growing number of nonunion lower cost producers.

Timken steelworkers take pay cut

A recent United Steelworkers settlement providing for cuts in compensation involved 6,000 employees of Timken Co. plants in Canton, Columbus, and Wooster, OH. Timken, which makes roller bearings as well as steel, had traditionally followed the settlement pattern set by the other companies bargaining as the Coordinating Committee Steel Companies. This was not possible in 1986 because the breakup of the bargaining association resulted in wide variations in settlement terms at the various companies. The companies contended that such variations in terms were necessary because of differences in their financial condition.

The Timken accord, which was preceded by a 1-month strike, provides for a 45-cent-an-hour pay cut, which will be restored in 15-cent increments at the end of each contract year. Immediately after the cut, average pay was $10.95 according to the union, and $11.84 according to the company.

The automatic cost-of-living pay allowance formula was modified to provide quarterly adjustments of 1 cent an hour for each 0.3-point rise in the BLS Consumer Price Index for Urban Wage Earners and Clerical Workers (1967=100). The provision becomes operative in the second year and reflects only possible CPI movement between 4 and 6 percent in that year and between 1.5 and 6 percent in the third year (previously, there was no 6-percent annual cap).

Pension rates were raised by $1.50 a month for each year of credited service, bringing the range of rates to $19–$22. Also, employees age 60 with 30 years of service were given two opportunities (during the last months of both 1986 and 1987) to retire with a $400 special pension supplement continuing to age 62.

In contrast with other 1986 settlements in the steel industry, Empire-Detroit Steel Co. and United Steelworkers Local 169 negotiated a 3-year contract that does not call for a cut in employee compensation. Company President John Frecka said, "We're profitable. I saw no reason to insist upon concessions." The contract does provide for possible annual performance awards of $150, $300, or $450, based on the company's financial results during the preceding 12 months. The accord, covering 1,100 workers in Mansfield, OH, also provides for a reopening of negotiations if the company encounters unexpected difficulties.

Paperworkers approve 'flexible' work assignments

In Rumford, ME, a $2\frac{1}{2}$-month strike against Boise Cascade Corp.'s largest paper mill ended when members of the United Paperworkers union approved a 3-year contract that included a "flexible work assignment" plan the company had been seeking since 1980. In 1984, Boise Cascade unilaterally introduced part of the plan by consolidating 12 job classifications into seven. In response to a complaint filed by the union, an arbitrator later overturned the company move. Nevertheless, the company claimed that the job consolidation improved productivity and morale during the 18 months it was in effect.

Under the bargained approach, Boise Cascade can shift production workers into other jobs, and have nonbargaining unit employees perform duties that had previously been generally restricted to bargaining unit workers. Another aspect of the plan permits management to train machine operators to perform routine maintenance and minor repairs, cutting the down time that had resulted when the operators waited for regular maintenance workers to do the work. There also was a change in duties of maintenance workers, as 12 job classifications were reduced to two: machinists and instrument machinists.

Wage provisions included a 50-cent-an-hour immediate increase, followed by 3-percent increases in the second and third years. According to a company official, the initial increase brought the average pay rate to $13.58 and the maximum for some machine tenders to more than $18. All employees on the payroll at the time of the contract signing also received a $1,000 lump-sum payment.

Boise-Cascade also achieved a cost saving under a new stretched pay progression schedule. New employees will be paid 80 percent ($7.77) of top base pay during their first 6 months, and full base pay thereafter.

The contract also provided for other cost reduction provisions, including time-and-one-half pay for all overtime work (previously, double time and, on occasion, quadruple time pay applied to some overtime work); elimination of some restrictions on operating the mill on Independence Day and Christmas; and adoption of a cost-containment plan for health insurance, including an 80-percent/20-percent coinsurance instead of the previous "first-dollar" coverage.

John Hancock provides 'cafeteria' benefits

The flexible or "cafeteria" approach to employee benefits is illustrated in a settlement between John Hancock Mutual Life Insurance Co. and the Teamsters union for nearly 300 claims processors in Dearborn, MI. All of the employees have "core" coverage consisting of a major medical plan with a $350 annual deductible and life insurance equal to each employee's annual compensation. Each employee also receives a number of weekly credits which can be used for alternate or additional benefits, such as a major medical plan with a $175 annual deductible, additional life insurance, dependent life insurance, a survivor's income plan, dental coverage, and vision coverage. Employees are permitted to select coverage in excess of their available credits if they assume the additional cost.

In addition to pension improvements, the 3-year contract provided for 5-percent annual pay increases and a lump-sum payment at the end of the first contract year equal to 7 percent of earnings during that year, followed by a 5-percent payment at the end of the second year and a 4-percent payment at the end of the final year.

Machinery workers take $1 hourly pay cut

Employees of Harnischfeger Corp., a machinery manufacturer, have agreed to a $1 an hour pay cut and other cost reduction changes in return for a possible share of profits and a company commitment to modernize the plants, located in the Milwaukee, WI, area. If the company meets the specified profit objective during the fiscal year beginning November 1, 1986, the 1,250 employees will receive $1.20 for each hour worked during the period. If the profit exceeds the objective, the distribution will be larger. If the company's profit level is "on target" after the first 6 months, the employees will then receive 25 percent of the expected full-year total payout.

Other terms of the 3-year contract negotiated by United Steelworkers Local 1114 included a suspension of automatic cost-of-living adjustments during the first 2 years and a 15-cent limit on adjustments during the final year; adoption of a two-tier compensation system providing for lower pay and benefit levels for new employees; lower vacation pay; and employee payment of a larger share of health insurance costs.

Harnischfeger's obligation for plant modernization was set at a minimum of $4.5 million over the contract term. Of that amount, the union will have a voice in spending $250,000 a year. The company also agreed to establish a job training fund of $30,000 a year to be administered by a joint committee.

Hospitals, nursing homes in New York settle

In New York City, 40,000 employees were covered by a settlement between the League of Voluntary Hospitals and Nursing Homes and Local 1199, Drug, Hospital and Health Care Employees Union. The League comprises 40 nonprofit hospitals and 9 nonprofit nursing homes. Earlier, five other nonprofit hospitals had settled on terms that were reportedly slightly more favorable to their 6,500 employees represented by Local 1199, which is part of the Retail, Wholesale and Department Store Union.

The League contract provides for an initial wage increase of 5 percent, retroactive to the August 28, 1984, ending date of the 47-day strike that preceded the 1984 settlement. This amount, to be paid in two lump-sums, represents a 5-percent increase scheduled under the 1984 accord but never implemented because of a dispute over the legality of the contract. (The 1984 settlement called for an additional 5-percent increase which went into effect as scheduled.)

The 3-year 1986 contract also calls for wage increases of 4 percent on November 1, 1986, and July 1, 1987, and 5 percent on July 1, 1988, all calculated on pay rates at the time of settlement, rather than being compounded. According to the union, average pay at the time of settlement was $370 a week for nurses, nurses' aides, housekeeping and laboratory personnel, social workers, and clerical workers.

The union agreed to several changes intended to moderate the cost of the settlement. One was that entry pay rates were only increased 9 percent over the term, instead of 13 percent. Also, new employees will be paid 4 percent less than normal pay rates during their first year. In the benefits area, employers' financing of pensions was changed to an amount equal to 7 percent of each employee's base pay, from 8 percent of gross pay. (Despite this reduction, an existing surplus enabled the parties to request that the plan trustees raise benefits by 10 percent for current retirees, retroactive to January 1, 1985, and by the same amount for future retirees.) Health insurance benefits were not changed, but the parties did adopt a cost-containment plan calling for such measures as a second opinion requirement before nonemergency surgery.

Food stores settlements

In Washington, DC, and nearby Maryland and Virginia, 18,500 employees of Safeway Stores Inc. and Giant Food Inc. were covered by a 3-year contract negotiated by Local 400 of the United Food and Commercial Workers. Similar terms also were negotiated by Local 27 for 7,000 employees in the Baltimore, MD, area.

Under the Local 400 settlement, employees hired prior to the October 1983 effective date of the prior contract did not receive wage increases. However, they will receive six semiannual lump-sum payments, each ranging from $175 to $500, depending on their assignment and number of hours worked. Workers hired after October 1983 will receive wage increases of $1.30 an hour, narrowing the differential with the longer service employees that resulted from adoption of a two-tier pay system in 1983.

The negotiators eliminated two-tier insurance benefits by adopting a uniform program for full-time employees and another less generous program for part-time employees.

Pension rates for employees hired prior to October 1983 were increased to $32 a month (from $20) for each year of credited future service for full-time employees, and to $20 (from $16) for part-timers. For employees hired later, the rates were increased to $13.20 for full-time workers and to $6.60 for part-timers. All of the 2,300 employees who retired prior to January 1, 1986, will receive 3-percent increases in their benefits on January 1 of 1987, 1988, and 1989.

Elsewhere in the industry, 650 members of United Food and Commercial Workers Local 23 agreed to pay cuts ranging from 24 cents to $1.15 an hour in a settlement with 12 Kroger Co. stores in eastern Ohio and nearby West Virginia. According to a company official, the pay cuts and other negotiated labor-cost savings could lead to expansion of operations in the Ohio Valley area, despite intense competition from nonunion stores.

The impact of the pay cut will be reduced by a provision for one-time lump-sum payments in late 1986 equal to the individual's cut in hourly pay multiplied by the number of hours worked between October 1985 and October 1986. There will not be any other such payments under the 5-year contract, but a new profit-sharing plan provides for possible annual distributions beginning in March 1988. Each worker's share of any distribution will be proportional to earnings lost as a result of the pay cut. In each of the last 2 years of the contracts, full-time employees will be guaranteed minimum payments of $300 and part-timers will be guaranteed $150.

Other changes that will reduce labor costs include a "buy out" offer under which top-scale full-time employees will receive $8,000 for resigning and top-scale part-timers will receive $4,000; 5 weeks maximum paid vacation, instead of 6 weeks; two paid personal leave days per year, instead of five; a $19.88 reduction in Kroger's $247.88 a month financing of insurance benefits; and expanded duties for meat clerks. Kroger estimated that all of the contract changes would result in a cost savings of about $2 an hour.

Hotel employees settle

More than 20,000 members of the Hotel Employees and Restaurant Employees were covered by settlements in three cities.

In Atlantic City, NJ, workers settled with seven casino hotels, ending a 1-day strike. The settlement covered 13,000 people, including employees of three operations that were not struck in return for assurances that they would accept the same terms as the other casino hotels. The settlement, reached under a contract reopening provision, extended the contract by 1 year, and provides for 10- to 20-cent-an-hour pay increases in 1986 and 1987.

In Washington, DC, Local 25 negotiated a 3-year contract that covered more than 6,000 employees of 17 hotels in the employers' bargaining association and 11 other hotels that accepted the same terms. The accord provides for 5-percent pay increases in each year, bringing the average pay of housekeepers, dishwashers, and food service workers to $8 an hour.

In San Francisco, Local 2 settled for 2,150 employees of six large hotels and was pressing 32 hotels to accept the same terms. During the 3-year contract term, employees will receive annual pay increases of 15 cents an hour for those who receive tips and 35 cents for those who do not, as well as improvements in overtime pay, sick leave, and medical and pension benefits.

Home work proposed in producing ladies apparel

In a move that drew criticism and vows of legal action from organized labor, the Department of Labor proposed regulations to allow employees in six industries to work in their homes, as long as their employers get a Government certificate. Secretary of Labor William Brock said that "because of the nationwide interest in home work employment," the period for public comment on the proposal would be 60 days.

The industries that would be affected are the production of women's apparel, jewelry, gloves and mittens, buttons and buckles, handkerchiefs, and embroidery. The proposal came after an 18-month study of the effectiveness of the certification plan that was instituted in the knitted outerwear industry in December 1984. In that industry, home work is permitted after employers register with the Department of Labor so that their adherence to minimum wage, child labor, and other laws can be monitored.

Jay Mazur, President of the Ladies Garment Workers, said the proposed rules give "the green light to thousands of sweatshop operators throughout this country who exploit our most vulnerable workers." He predicted that thousands of factory workers in the six industries would lose their jobs or suffer a decline in their "already modest standard of living due to competition with sweatshop wages."

Stephen Goodrick, executive director of the Center on National Labor Policy, a lobbying and legal advocacy group, said the rule change will "liberate this section of the economy for entrepreneurial growth and productivity." He also said that 70,000 people are already engaged in illegal commercial work in the home and that legalizing the practice would raise government tax revenue by $50 million a year.

Glass container workers restore forgone pay

In the glass container industry, 17,000 workers negotiated restoration of a 31-cent-an-hour scheduled wage increase they had given up in 1985 when the employers were experiencing financial problems. The 1985 settlements had also extended the existing agreement by 1 year, to March 31, 1987. Under the 1986 settlement, which came during a period of improved employer profits, the contract was extended to March 31, 1990, with provision for a 21-cent wage increase in April 1987, 26 cents in April 1988, and 31 cents in April 1989. Prior to the settlement, the average wage was $9.40.

Pensions were increased effective in April 1988 for all employees who retire after April 1986. The employees' cost for health insurance was increased, but the companies did agree to pay more into a trust fund for retirees' health coverage. They also agreed to assume the workers' 50-percent share of a 10-cent-an-hour payment into an industry promotion fund.

The companies that settled with the Glass, Pottery, Plastic and Allied Workers were Brockway Inc., for 6,500 workers; Anchor-Hocking Corp. (4,300); Foster Forbes Glass Co. (3,000); Incon Packaging Inc. (2,100); and Ball Corp. (1,100). Negotiations were continuing with Owens Illinois Inc. for 12,000 workers and with Diamond-Bathurst for 5,000.

Teachers' agreements

Members of the Portland (OR) Association of Teachers negotiated a 3-year contract that calls for wage increases of 5 percent in the first year and 4.5 percent in the second year. In the third year, the 3,200 teachers will receive an increase of at least 3.5 percent but not more than 6.5 percent, depending on the movement of the Portland area Consumer Price Index. After the first-year increase, salaries ranged from $17,732 for starting teachers to $33,240 for teachers with a master's degree plus 45 credit hours of academic training and 18 years of experience.

Other terms included a doubling of college tuition reimbursement, to six credit hours per year.

In Little Rock, AR, 1,100 teachers received two payments totaling $520 to $971 by agreeing to add $6\frac{1}{4}$ days to the 1985-86 school year. The payment resulted when the school district received a Federal grant for magnet schools, permitting the district to distribute to teachers $1.6 million it had budgeted from its own funds for the project.

Early in 1986, the district gave each teacher $475 and was planning to distribute the balance of the $1.6 million in the same way, but the State Board of Education ruled that this could be done only if the school year was extended, leading to the $6\frac{1}{4}$-day extension and an additional $45 to $496 payment, varying according to each teacher's salary scale.

The payments did not become part of the teachers' contractual salary scale for the school year, which was raised 1.61 percent on September 9, 1985, under the contract negotiated then. This brought the salary range to $14,098 to $26,308 a year, depending on education and length of service.

Ohio State workers get initial contract

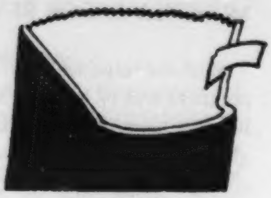
About 35,000 State employees were covered by an initial contract negotiated by the Ohio Civil Service Employees Association, which affiliated with the State, County and Municipal Employees union in 1984. Ohio State employees gained the right to bargain on wages and benefits under 1984 legislation.

Wage provisions included an immediate increase of 58 cents an hour or 7 percent (whichever is greater) and a $450 bonus for those on the payroll before April 1, 1986; an increase of 44 cents or 5 percent, in the second year; and 65 cents or 7 percent in the third year, plus a $300 bonus on November 1, 1988, for those on the payroll on October 15, 1988.

Prior to the initial pay increase, average hourly rates for the eight units of workers involved ranged from $6.63 for food service, custodial, and laundry workers to $11.64 for engineers, biologists, and geologists.

Benefit changes included an eleventh paid holiday; 10 annual sick leave days payable at 100 percent, instead of 7 days payable at 90 percent; three personal leave days and prorated paid vacation for part-time employees; and adoption of a program to aid corrections officers suffering aftereffects of being taken hostage. □

Book Reviews



Managerial discretion in the workplace

Management Rights: A Legal and Arbitral Analysis. By Marvin Hill, Jr. and Anthony V. Sinicropi. Washington, The Bureau of National Affairs, Inc., 1986. 560 pp. $40.

Source books that deal with questions of legal rights for practitioners usually face the kind of dilemma that confronts do-it-yourself guides to medicine: offer summary descriptions and readers may not be able to tell when they have a problem, but present a detailed discussion and they may start to think that they can cut the doctor out of the process. Marvin Hill, Jr. and Anthony V. Sinicropi have avoided that dilemma by writing a book that is not for practitioners in the usual sense but for the labor relations "doctors"—arbitrators and those who present arbitration cases.

The book focuses on the issue of management rights under collective bargaining agreements—situations where the agreements do not clearly specify the rights of the parties. In fact, the book's theme is much broader than what many arbitrators will think of as management rights issues, in that it goes beyond such common problems as technological change and job assignment to consider virtually every set of circumstances where contracts may be silent. This broad coverage has the great advantage of presenting a single source for all such issues. However, some issues, such as employee discipline and discharge and seniority decisions, have already been discussed in depth elsewhere, and readers may want to consult the existing literature.

The book traces the evolution of management rights primarily through a detailed analysis of arbitration decisions, although rulings of the National Labor Relations Board, case law, and legislation are also considered. It begins by discussing some general issues, such as the important role of past practice in determining management rights, and then addresses various areas of those rights in turn. Perhaps the most interesting section of the book is the discussion of areas where management's interests may conflict with employees' interests in privacy, for example, the use of polygraph tests and surveillance and searches in the workplace. Separate discussions of management's rights with respect to medical and psychiatric screening, including drug testing and the handling of employees with AIDS, make the book very topical.

Management Rights is obviously not a book for everyone. Nonarbitrators involved in day-to-day labor relations should of course be aware that the analyses of the issues here will not necessarily help determine how a given arbitrator might rule on a particular issue because the precedential value of arbitration decisions is limited at best. In terms of reading, the book is filled with quotations and citations that combined with the often convoluted path of arbitration decisions make it considerably slower going than, say, your average gothic novel.

But this detail is precisely what results in a very useful book, especially for arbitrators and lawyers who have limited experience with some of the issues raised here because they can quickly see the line of reasoning in previous decisions. By identifying the trends in arbitration decisions in the difficult area of management's rights, the authors have traveled through relatively uncharted waters and have contributed a real service to the field of labor relations.

Labor in a changing America

Out of Work: The First Century of Unemployment in Massachusetts. By Alexander Keyssar. New York, Cambridge University Press, 1986. 469 pp. $49.50, cloth; $14.95, paper.

Alexander Keyssar's book is a scholarly contribution and a valuable resource to economists, labor historians, trade unionists, and policymakers. Keyssar investigates labor markets from the 1870's to the 1920's, a period often passed over by present-day economists and economic historians who tend to direct more attention to the Great Depression and Industrial Revolution in the United States. (John A. Garraty's *Unemployment in History: Economic Thought and Public Policy* and Gordon, Edwards, and Reich's *Segmented Work, Divided Workers* are notable exceptions.) He blends an abundance—sometimes an overabundance—of empirical data with impressionistic evidence depicting the extent and character of the period's unemployment.

Idle labor is a centuries-old phenomenon. But as the structure of production shifted toward manufacturing throughout the 19th century, the consequences for a typical jobless worker became harsher by the 1870's with the disappearance of alternative activities such as household production.

With the stage set, Keyssar then offers four original viewpoints in *Out of Work*. First is his chronicling of the unbelievably slow pace at which unemployment came to be regarded as a conspicuous social problem. Public perception only gradually evolved from considering unemployment as an individual, labor supply problem to understanding it as a labor demand problem endemic to the industrial economy. The tendency for chronic unemployment to uproot many working men was initially regarded as "the tramp problem." Reforms to prevent unemployment or its hardship were routinely rebuffed until 1915, when government and business began to recognize the threat of unemployment to the existing social structure. Economists viewed unemployment as transitory and thus proved little help in remedying it.

Keyssar also describes how chronic unemployment gradually transformed trade unions from organizations promoting universal policies to benefit all labor such as a shorter workweek to policies pursuing exclusionist measures, for example, restricting apprenticeships in order to protect members' jobs.

The author creatively uses the available data to construct unemployment frequencies—the percentage of workers unemployed at some point during the year. The data reveal startlingly high frequencies upwards of 30 percent in the depths of a downturn and surprisingly high proportions in prosperous times as well.

Keyssar's final and most important point derives from these frequencies. The 1870–1920's era was apparently characterized by a substantial *volatility* in employment. Income insecurity rather than low incomes per se was thus the key problem workers faced. Their vulnerability to sudden layoff and income loss cut across occupations, industries, ethnic groups, and gender. One immediate and two subsequent developments from this era could be traced to the widespread income insecurity. Keyssar colorfully illustrates how workers established ad hoc methods of coping with the persistent threat of unemployment. Children were periodically sent to work and debt was commonly incurred with local shopkeepers. After 1915, businesses began to discover the costs associated with high labor turnover. Some implemented progressive personnel practices including the offer of continuous employment over seasonal (but not cyclical) fluctuations, work sharing, and a rationalized allocation of layoffs based on seniority. The modern implicit contract and its increased predictability of incomes were thus born. Finally, the widespread income insecurity ultimately led to the adoption of unemployment insurance programs.

Despite its merits, *Out of Work* has some shortcomings. The author often fails to clearly distinguish structural, frictional, and cyclical sources of unemployment, essential in assessing the consequent hardship. Also, there is no direct mention of productivity growth in industry and its potential role in suppressing employment levels, shortening the workweek, or varying wages and living standards. In addition, Keyssar often subtly implicates but never really outright indicts the widely accepted employment-at-will doctrine as the ultimate source of the era's employment volatility. This is perhaps the principle message and it is left to the reader to infer. Finally, it is also left to the reader to gauge the *relative* condition of labor because we are given no reference point. Perhaps some of the redundancy that appears throughout the book could be sacrificed for some comparisons to unemployment frequencies, the composition of the "reserve army" of unemployed, and the use of short-time versus layoffs in more recent years.

A final comparison Keyssar misses is the parallel to the current fad of identifying laissez faire as the policy solution rather than the problem. Even with these shortcomings, *Out of Work* reminds us that labor market instability and unemployment were the cause of union and government intervention rather than the result of it.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force, employment, unemployment, collective bargaining settlements, consumer, producer, and international prices, productivity, international comparisons, and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described, key definitions are given, notes on the data are set forth, and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. (Seasonally adjusted data appear in tables 1–3, 4–10, 13, 14, 17, and 18.) Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are seasonally adjusted with a procedure called X-11 ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method previously used by BLS. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada, Catalogue No. 12-564E, February 1980). The second change is that seasonal factors are calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at midyear for the July-December period. However, revisions of historical data continue to be made only at the end of each calendar year.

Seasonally adjusted labor force data in tables 1 and 4–10 were revised in the February 1986 issue of the *Review*, to reflect experience through 1985.

Annual revisions of the seasonally adjusted payroll data shown in tables 13, 14, and 18 were made in the July 1986 *Review* using the X-11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in table 42 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the Hourly Earnings Index in table 17—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The $2 (or any other resulting values) are described as "real," "constant," or "1967" dollars.

Additional information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule preceding these general notes. More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in *Employment and Earnings*, a monthly publication of the Bureau. More data from the household survey are published in the two-volume data book—*Labor Force Statistics Derived From the Current Population Survey*, Bulletin 2096. More data from the establishment survey appear in two data books—*Employment, Hours, and Earnings, United States*, and *Employment, Hours, and Earnings, States and Areas*, and the annual supplements to these data books. More detailed information on employee compensation and collective bargaining settlements is published in the monthly periodical, *Current Wage Developments*. More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report*, and *Producer Prices and Price Indexes*. Detailed data on all of the series in this section are provided in the *Handbook of Labor Statistics*, which is published biennally by the Bureau. BLS bulletins are issued covering productivity, injury and illness, and other data in this section. Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.
n.e.s. = not elsewhere specified.

COMPARATIVE INDICATORS
(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-to-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonagricultural payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in: consumer prices for all urban consumers; producer prices by stage of processing; and the overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data. For detailed descriptions of each data series, see BLS *Handbook of Methods*, Volumes I and II, Bulletins 2134–1 and 2134–2 (Bureau of Labor Statistics, 1982 and 1984, respectively), as well as the additional bulletins, articles, and other publications noted in the separate sections of the *Review*'s "Current Labor Statistics Notes." Historical data for many series are provided in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). Users may also wish to consult *Major Programs, Bureau of Labor Statistics*, Report 718 (Bureau of Labor Statistics, 1985).

EMPLOYMENT DATA

(Tables 1; 4–21)

Household survey data

Description of the series

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 59,500 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all civilians who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. Members of the Armed Forces stationed in the United States are also included in the employed total. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **overall unemployment rate** represents the number unemployed as a percent of the labor force, including the resident Armed Forces. The **civilian unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **labor force** consists of all employed or unemployed civilians plus members of the Armed Forces stationed in the United States. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons who are retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy, and members of the Armed Forces stationed in the United States. The **labor force participation rate** is the proportion of the noninstitutional population that is in the labor force. The **employment-population ratio** is total employment (including the resident Armed Forces) as a percent of the noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 4–10 are seasonally adjusted, based on the seasonal experience through December 1985.

Additional sources of information

For detailed explanations of the data, see BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 1, and for additional data, *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). A detailed description of the Current Population Survey as well as additional data are available in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*. Historical data from 1948 to 1981 are available in *Labor Force Statistics Derived from the Current Population Survey: A Databook*, Vols. I and II, Bulletin 2096 (Bureau of Labor Statistics, 1982).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Establishment survey data

Description of the series

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by more than 250,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include working supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12–17 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in the following industries: transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and

services. These groups account for about four-fifths of the total employment on private nonagricutural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index, introduced in the May 1983 *Review*, represents the percent of 185 nonagricultural industries in which employment was rising over the indicated period. One-half of the industries with unchanged employment are counted as rising. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. The diffusion index is useful for measuring the dispersion of economic gains or losses and is also an economic indicator.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1986 data, published in the July 1986 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Unadjusted data have been revised back to April 1984; seasonally adjusted data have been revised back to January 1981. These revisions were published in the *Supplement to Employment and Earnings* (Bureau of Labor Statistics, 1986). Unadjusted data from April 1985 forward, and seasonally adjusted data from January 1982 forward are subject to revision in future benchmarks.

In the establishment survey, estimates for the 2 most recent months are based on incomplete returns and are published as preliminary in the tables (13 to 16 in the *Review*). When all returns have been received, the estimates are revised and published as final in the third month of their appearance. Thus, August data are published as preliminary in October and November and as final in December. For the same reason, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Thus, second-quarter data are published as preliminary in August and September and as final in October.

Additional sources of information

Detailed data from the establishment survey are published monthly in the BLS periodical, *Employment and Earnings*. Earlier comparable unadjusted and seasonally adjusted data are published in *Employment, Hours, and Earnings, United States, 1909–84*, Bulletin 1312–12 (Bureau of Labor Statistics, 1985) and its annual supplement. For a detailed discussion of the methodology of the survey, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 2. For additional data, see *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Unemployment data by State

Description of the series

Data presented in this section are obtained from two major sources—the Current Population Survey (CPS) and the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act and the Public Works and Economic Development Act. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for 11 States—California, Florida, Illinois, Massachusetts, Michigan, New York, New Jersey, North Carolina, Ohio, Pennsylvania, and Texas—are obtained directly from the CPS, because the size of the sample is large enough to meet BLS standards of reliability. Data for the remaining 39 States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates for the 11 States are revised to new population controls. For the remaining States and the District of Columbia, data are benchmarked to annual average CPS levels.

Additional sources of information

Information on the concepts, definitions, and technical procedures used to develop labor force data for States and sub-State areas as well as additional data on sub-States are provided in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*, and the annual report, *Geographic Profile of Employment and Unemployment* (Bureau of Labor Statistics). See also *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 4.

COMPENSATION AND WAGE DATA

(Tables 1–3; 22–29)

COMPENSATION AND WAGE DATA are gathered by the Bureau from business establishments, State and local governments, labor unions, collective bargaining agreements on file with the Bureau, and secondary sources.

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It uses a fixed market basket of labor—similar in concept to the Consumer Price Index's fixed market basket of goods and services—to measure change over time in employer costs of employing labor. The index is not seasonally adjusted.

Statistical series on total compensation costs and on wages and salaries are available for private nonfarm workers excluding proprietors, the self-employed, and household workers. Both series are also available for State and local government workers and for the civilian nonfarm economy, which consists of private industry and State and local government workers combined. Federal workers are excluded.

The Employment Cost Index probability sample consists of about 2,200 private nonfarm establishments providing about 12,000 occupational observations and 700 State and local government establishments providing

3,500 occupational observations selected to represent total employment in each sector. On average, each reporting unit provides wage and compensation information on five well-specified occupations. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Beginning with June 1986 data, fixed employment weights from the 1980 Census of Population are used each quarter to calculate the indexes for civilian, private, and State and local governments. (Prior to June 1986, the employment weights are from the 1970 Census of Population.) These fixed weights, also used to derive all of the industry and occupation series indexes, ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the bargaining status, region, and metropolitan/nonmetropolitan area series, however, employment data by industry and occupation are not available from the census. Instead, the 1980 employment weights are reallocated within these series each quarter based on the current sample. Therefore, these indexes are not strictly comparable to those for the aggregate, industry, and occupation series.

Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980 to produce, when combined with the wages and salaries series, a measure of the percent change in employer costs for employee total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the *civilian* nonfarm economy (excluding Federal employees). Historical indexes (June 1981 = 100) of the quarterly rates of change are presented in the May issue of the BLS monthly periodical, *Current Wage Developments*.

Additional sources of information

For a more detailed discussion of the Employment Cost Index, see the *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 11, and the following *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor'," July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; "Estimation procedures for the Employment Cost Index," May 1982; and "Introducing new weights for the Employment Cost Index," June 1985.

Data on the ECI are also available in BLS quarterly press releases issued in the month following the reference months of March, June, September, and December; and from the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Collective bargaining settlements

Description of the series

Collective bargaining settlements data provide statistical measures of negotiated adjustments (increases, decreases, and freezes) in compensation (wage and benefit costs) and wages alone, quarterly for private industry and semiannually for State and local government. Compensation measures cover all collective bargaining situations involving 5,000 workers or more and wage measures cover all situations involving 1,000 workers or more. These data, covering private nonagricultural industries and State and local governments, are calculated using information obtained from bargaining agreements on file with the Bureau, parties to the agreements, and secondary sources, such as newspaper accounts. The data are not seasonally adjusted.

Settlement data are measured in terms of future specified adjustments: those that will occur within 12 months after contract ratification—first-year—and all adjustments that will occur over the life of the contract expressed as an average annual rate. Adjustments are worker weighted. Both first-year and over-the-life measures exclude wage changes that may occur under cost-of-living clauses that are triggered by future movements in the Consumer Price Index.

Effective wage adjustments measure all adjustments occurring in the reference period, regardless of the settlement date. Included are changes from settlements reached during the period, changes deferred from contracts negotiated in earlier periods, and changes under cost-of-living adjustment clauses. Each wage change is worker weighted. The changes are prorated over all workers under agreements during the reference period yielding the average adjustment.

Definitions

Wage rate changes are calculated by dividing newly negotiated wages by the average hourly earnings, excluding overtime, at the time the agreement is reached. Compensation changes are calculated by dividing the change in the value of the newly negotiated wage and benefit package by existing average hourly compensation, which includes the cost of previously negotiated benefits, legally required social insurance programs, and average hourly earnings.

Compensation changes are calculated by placing a value on the benefit portion of the settlements at the time they are reached. The cost estimates are based on the assumption that conditions existing at the time of settlement (for example, methods of financing pensions or composition of labor force) will remain constant. The data, therefore, are measures of negotiated changes and not of total changes in employer cost.

Contract duration runs from the effective date of the agreement to the expiration date or first wage reopening date, if applicable. Average annual percent changes over the contract term take account of the compounding of successive changes.

Notes on the data

Care should be exercised in comparing the size and nature of the settlements in State and local government with those in the private sector because of differences in bargaining practices and settlement characteristics. A principal difference is the incidence of cost-of-living adjustment (COLA) clauses which cover only about 2 percent of workers under a few local government settlements, but cover 50 percent of workers under private sector settlements. Agreements without COLA's tend to provide larger specified wage increases than those with COLA's. Another difference is that State and local government bargaining frequently excludes pension benefits which are often prescribed by law. In the private sector, in contrast, pensions are typically a bargaining issue.

Additional sources of information

For a more detailed discussion on the series, see the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 10. Comprehensive data are published in press releases issued quarterly (in January, April, July, and October) for private industry, and semi-

annually (in February and August) for State and local government. Historical data and additional detailed tabulations for the prior calendar year appear in the April issue of the BLS monthly periodical, *Current Wage Developments*.

Work stoppages

Description of the series

Data on **work stoppages** measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of time lost because of stoppage.

Data are largely from newspaper accounts and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

Additional sources of information

Data for each calendar year are reported in a BLS press release issued in the first quarter of the following year. Monthly data appear in the BLS monthly periodical, *Current Wage Developments*. Historical data appear in the *BLS Handbook of Labor Statistics*.

Other compensation data

Other BLS data on pay and benefits, not included in the Current Labor Statistics section of the *Monthly Labor Review*, appear in and consist of the following:

Industry Wage Surveys provide data for specific occupations selected to represent an industry's wage structure and the types of activities performed by its workers. The Bureau collects information on weekly work schedules, shift operations and pay differentials, paid holiday and vacation practices, and information on incidence of health, insurance, and retirement plans. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Monthly Labor Review*.

Area Wage Surveys annually provide data for selected office, clerical, professional, technical, maintenance, toolroom, powerplant, material movement, and custodial occupations common to a wide variety of industries in the areas (labor markets) surveyed. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Review*.

The National Survey of Professional, Administrative, Technical, and Clerical Pay provides detailed information annually on salary levels and distributions for the types of jobs mentioned in the survey's title in private employment. Although the definitions of the jobs surveyed reflect the duties and responsibilities in private industry, they are designed to match specific pay grades of Federal white-collar employees under the General Schedule pay system. Accordingly, this survey provides the legally required information for comparing the pay of salaried employees in the Federal civil service with pay in private industry. (See Federal Pay Comparability Act of 1970, 5 U.S.C. 5305.) Data are published in a BLS news release issued in the summer and in a bulletin each fall; summaries and analytical articles also appear in the *Review*.

Employee Benefits Survey provides nationwide information on the incidence and characteristics of employee benefit plans in medium and large establishments in the United States, excluding Alaska and Hawaii. Data are published in an annual BLS news release and bulletin, as well as in special articles appearing in the *Review*.

PRICE DATA
(Tables 2; 30–41)

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI–W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all urban consumer index (CPI–U) introduced in 1978 is representative of the 1972–73 buying habits of about 80 percent of the noninstitutional population of the United States at that time, compared with 40 percent represented in the CPI–W. In addition to wage earners and clerical workers, the CPI–U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 24,000 retail establishments and 24,000 tenants in 85 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 28 major urban centers are presented in table 31. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI–U. A rental equivalence method replaced the

asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes.

Additional sources of information

For a discussion of the general method for computing the CPI, see *BLS Handbook of Methods, Volume II, The Consumer Price Index*, Bulletin 2134–2 (Bureau of Labor Statistics, 1984). The recent change in the measurement of homeownership costs is discussed in Robert Gillingham and Walter Lane, "Changing the treatment of shelter costs for homeowners in the CPI," *Monthly Labor Review*, June 1982, pp. 9–14.

Additional detailed CPI data and regular analyses of consumer price changes are provided in the *CPI Detailed Report*, a monthly publication of the Bureau. Historical data for the overall CPI and for selected groupings may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Producer Price Indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 60,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The stage of processing structure of Producer Price Indexes organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1976, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

Notes on the data

Beginning with the January 1986 issue, the *Review* is no longer presenting tables of Producer Price Indexes for commodity groupings, special composite groups, or SIC industries. However, these data will continue to be presented in the Bureau's monthly publication *Producer Price Indexes*.

The Bureau has completed the first major stage of its comprehensive overhaul of the theory, methods, and procedures used to construct the Producer Price Indexes. Changes include the replacement of judgment sampling with probability sampling techniques; expansion to systematic coverage of the net output of virtually all industries in the mining and manufacturing sectors; a shift from a commodity to an industry orientation; the exclusion of imports from, and the inclusion of exports in, the survey universe; and the respecification of commodities priced to conform to Bureau of the Census definitions. These and other changes have been phased in gradually since 1978. The result is a system of indexes that is easier to use in conjunction with data on wages, productivity, and employment and other series that are organized in terms of the Standard Industrial Classification and the Census product class designations.

Additional sources of information

For a discussion of the methodology for computing Producer Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 7.

Additional detailed data and analyses of price changes are provided monthly in *Producer Price Indexes*. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

International price indexes

Description of the series

The BLS **International Price Program** produces quarterly export and import price indexes for nonmilitary goods traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts: it includes corporations, businesses, and individuals but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents. With publication of an all-import index in February 1983 and an all-export index in February 1984, all U.S. merchandise imports and exports now are represented in these indexes. The reference period for the indexes is 1977 = 100, unless otherwise indicated.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected quarterly by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first 2 weeks of the third month of each calendar quarter—March, June, September, and December. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined by the 4- and 5-digit level of detail of the Standard Industrial Trade Classification System (SITC). The calculation of indexes by SITC category facilitates the comparison of U.S. price trends and sector production with similar data for other countries. Detailed indexes are also computed and published on a Standard Industrial Classification (SIC-based) basis, as well as by end-use class.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. Price relatives are assigned equal importance within each weight category and are then aggregated to the SITC level. The values assigned to each weight category are based on trade value figures compiled

by the Bureau of the Census. The trade weights currently used to compute both indexes relate to 1980.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's quarterly questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

For the export price indexes, the preferred pricing basis is f.a.s. (free alongside ship) U.S. port of exportation. When firms report export prices f.o.b. (free on board), production point information is collected which enables the Bureau to calculate a shipment cost to the port of exportation. An attempt is made to collect two prices for imports. The first is the import price f.o.b. at the foreign port of exportation, which is consistent with the basis for valuation of imports in the national accounts. The second is the import price c.i.f. (cost, insurance, and freight) at the U.S. port of importation, which also includes the other costs associated with bringing the product to the U.S. border. It does not, however, include duty charges.

Additional sources of information

For a discussion of the general method of computing International Price Indexes, see BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 8.

Additional detailed data and analyses of international price developments are presented in the Bureau's quarterly publication *U.S. Import and Export Price Indexes* and in occasional *Monthly Labor Review* articles prepared by BLS analysts. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

PRODUCTIVITY DATA
(Tables 2; 42–47)

U. S. productivity and related data

Description of the series

The productivity measures relate real physical output to real input. As such, they encompass a family of measures which include single factor input measures, such as output per unit of labor input (output per hour) or output per unit of capital input, as well as measures of multifactor productivity (output per unit of labor and capital inputs combined). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the value of goods and services in constant prices produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the value of goods and services in constant dollars produced per unit of capital services input.

Multifactor productivity is the ratio output per unit of labor and capital inputs combined. Changes in this measure reflect changes in a number of factors which affect the production process such as changes in technology, shifts in the composition of the labor force, changes in capacity utilization, research and development, skill and efforts of the work force, management, and so forth. Changes in the output per hour measures reflect the impact of these factors as well as the substitution of capital for labor.

Compensation per hour is the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, and the wages, salaries, and supplementary payments for the self-employed (except for nonfinancial corporations in which there are no self-employed)—the sum divided by hours paid for. **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current dollar value of output and dividing by output. **Unit nonlabor costs** contain all the components of unit nonlabor payments *except* unit profits.

Unit profits include corporate profits and the value of inventory adjustments per unit of output.

Hours of all persons are the total hours paid of payroll workers, self-employed persons, and unpaid family workers.

Capital services is the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Labor and capital inputs combined are derived by combining changes in labor and capital inputs with weights which represent each component's share of total output. The indexes for capital services and combined units of labor and capital are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Output measures for the business sector and the nonfarm businesss sector exclude the constant dollar value of owner-occupied housing, rest of world, households and institutions, and general government output from the constant dollar value of gross national product. The measures are derived from data supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are developed from data of the Bureau of Labor Statistics and the Bureau of Economic Analysis.

The productivity and associated cost measures in tables 42–44 describe the relationship between output in real terms and the labor time and capital services involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input. Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; capital investment; level of output; utilization of capacity, energy, and materials; the organization of production; managerial skill; and the characteristics and efforts of the work force.

Additional sources of information

Descriptions of methodology underlying the measurement of output per hour and multifactor productivity are found in the BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 13. Historical data for selected industries are provided in the Bureau's *Handbook of Labor Statistics*, 1985, Bulletin 2217.

INTERNATIONAL COMPARISONS
(Tables 45–47)

Labor force and unemployment

Description of the series

Tables 45 and 46 present comparative measures of the labor force, employment, and unemployment—approximating U.S. concepts—for the United States, Canada, Australia, Japan, and six European countries. The unemployment statistics (and, to a lesser extent, employment statistics) published by other industrial countries are not, in most cases, comparable to U.S. unemployment statistics. Therefore, the Bureau adjusts the figures for selected countries, where necessary, for all known major definitional differences. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country.

Definitions

For the principal U.S. definitions of the **labor force**, **employment**, and **unemployment**, see the Notes section on EMPLOYMENT DATA: Household Survey Data.

Notes on the data

The adjusted statistics have been adapted to the age at which compulsory schooling ends in each country, rather than to the U.S. standard of 16 years of age and over. Therefore, the adjusted statistics relate to the population age 16 and over in France, Sweden, and from 1973 onward, Great Britain; 15 and over in Canada, Australia, Japan, Germany, the Netherlands, and prior to 1973, Great Britain; and 14 and over in Italy. The institutional population is included in the denominator of the labor force participation rates and employment-population ratios for Japan and Germany; it is excluded for the United States and the other countries.

In the U.S. labor force survey, persons on layoff who are awaiting recall to their job are classified as unemployed. European and Japanese layoff practices are quite different in nature from those in the United States; therefore, strict application of the U.S. definition has not been made on this point. For further information, see *Monthly Labor Review*, December 1981, pp. 8–11.

The figures for one or more recent years for France, Germany, Great Britain, Italy, and the Netherlands are calculated using adjustment factors based on labor force surveys for earlier years and are considered preliminary. The recent-year measures for these countries are, therefore, subject to revision whenever data from more current labor force surveys become available.

Additional sources of information

For further information, see *International Comparisons of Unemployment*, Bulletin 1979 (Bureau of Labor Statistics, 1978), Appendix B and unpublished Supplements to Appendix B, available on request. The statistics are also analyzed periodically in the *Monthly Labor Review*. Additional historical data, generally beginning with 1959, are published in the *Handbook of Labor Statistics* and are available in unpublished statistical supplements to Bulletin 1979.

Manufacturing productivity and labor costs

Description of the series

Table 47 presents comparative measures of manufacturing labor productivity, hourly compensation costs, and unit labor costs for the United States, Canada, Japan, and nine European countries. These measures are limited to trend comparisons—that is, intercountry series of changes over time—rather than level comparisons because reliable international comparisons of the levels of manufacturing output are unavailable.

Definitions

Output is constant value output (value added), generally taken from the national accounts of each country. While the national accounting methods for measuring real output differ considerably among the 12 countries, the use of different procedures does not, in itself, connote lack of comparability—rather, it reflects differences among countries in the availability and reliability of underlying data series.

Hours refer to all employed persons including the self-employed in the United States and Canada; to all wage and salary employees in the other countries. The U.S. hours measure is hours paid; the hours measures for the other countries are hours worked.

Compensation (labor cost) includes all payments in cash or kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. In addition, for some countries, compensation is adjusted for other significant taxes on payrolls or employment (or reduced to reflect subsidies), even if they are not for the direct benefit of workers, because such taxes are regarded as labor costs. However, compensation does not include all items of labor cost. The costs of recruitment, employee training, and plant facilities and services—such as cafeterias and medical clinics—are not covered because data are not available for most countries. Self-employed workers are included in the U.S. and Canadian compensation figures by assuming that their hourly compensation is equal to the average for wage and salary employees.

Notes on the data

For most of the countries, the measures refer to total manufacturing as defined by the International Standard Industrial Classification. However, the measures for France (beginning 1959), Italy (beginning 1970), and the United Kingdom (beginning 1976), refer to manufacturing and mining less energy-related products and the figures for the Netherlands exclude petroleum refining from 1969 to 1976. For all countries, manufacturing includes the activities of government enterprises.

The figures for one or more recent years are generally based on current indicators of manufacturing output, employment, hours, and hourly compensation and are considered preliminary until the national accounts and other statistics used for the long-term measures become available.

Additional sources of information

For additional information, see the BLS *Handbook of Methods*, Bulletin 2134-1 (Bureau of Labor Statistics, 1982), chapter 16, and periodic *Monthly Labor Review* articles. Historical data are provided in the Bureau's *Handbook of Labor Statistics*, Bulletin 2217, 1985. The statistics are issued twice per year—in a news release (generally in May) and in a *Monthly Labor Review* article (generally in December).

OCCUPATIONAL INJURY AND ILLNESS DATA

(Table 48)

Description of the series

The Annual Survey of Occupational Injuries and Illnesses is designed to collect data on injuries and illnesses based on records which employers in the following industries maintain under the Occupational Safety and Health Act of 1970: agriculture, forestry, and fishing; oil and gas extraction; construction; manufacturing; transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. Excluded from the survey are self-employed individuals, farmers with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies.

Because the survey is a Federal–State cooperative program and the data must meet the needs of participating State agencies, an independent sample is selected for each State. The sample is selected to represent all private industries in the States and territories. The sample size for the survey is dependent upon (1) the characteristics for which estimates are needed; (2) the industries for which estimates are desired; (3) the characteristics of the population being sampled; (4) the target reliability of the estimates; and (5) the survey design employed.

While there are many characteristics upon which the sample design could be based, the total recorded case incidence rate is used because it is one of the most important characteristics and the least variable; therefore, it requires the smallest sample size.

The survey is based on stratified random sampling with a Neyman allocation and a ratio estimator. The characteristics used to stratify the establishments are the Standard Industrial Classification (SIC) code and size of employment.

Definitions

Recordable occupational injuries and illnesses are: (1) occupational deaths, regardless of the time between injury and death, or the length of the illness; or (2) nonfatal occupational illnesses; or (3) nonfatal occupational injuries which involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment (other than first aid).

Occupational injury is any injury such as a cut, fracture, sprain, amputation, and so forth, which results from a work accident or from exposure involving a single incident in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to environmental factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday cases are cases which involve days away from work, or days of restricted work activity, or both.

Lost workday cases involving restricted work activity are those cases which result in restricted work activity only.

Lost workdays away from work are the number of workdays (consecutive or not) on which the employee would have worked but could not because of occupational injury or illness.

Lost workdays—restricted work activity are the number of workdays (consecutive or not) on which, because of injury or illness: (1) the employee was assigned to another job on a temporary basis; or (2) the employee worked at a permanent job less than full time; or (3) the employee worked at a permanently assigned job but could not perform all duties normally connected with it.

The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked even though able to work.

Incidence rates represent the number of injuries and/or illnesses or lost workdays per 100 full-time workers.

Notes on the data

Estimates are made for industries and employment-size classes and for severity classification: fatalities, lost workday cases, and nonfatal cases without lost workdays. Lost workday cases are separated into those where the employee would have worked but could not and those in which work activity was restricted. Estimates of the number of cases and the number of days lost are made for both categories.

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses, or lost workdays, per 100 full-time employees. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Only a few of the available measures are included in the *Handbook of Labor Statistics*. Full detail is presented in the annual bulletin, *Occupational Injuries and Illnesses in the United States, by Industry*.

Comparable data for individual States are available from the BLS Office of Occupational Safety and Health Statistics.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration, respectively. Data from these organizations are included in BLS and State publications. Federal employee experience is compiled and published by the Occupational Safety and Health Administration. Data on State and local government employees are collected by about half of the States and territories; these data are not compiled nationally.

Additional sources of information

The Supplementary Data System provides detailed information describing various factors associated with work-related injuries and illnesses. These data are obtained from information reported by *employers* to State workers' compensation agencies. The Work Injury Report program examines selected types of accidents through an employee survey which focuses on the circumstances surrounding the injury. These data are not included in the *Handbook of Labor Statistics* but are available from the BLS Office of Occupational Safety and Health Statistics.

The definitions of occupational injuries and illnesses and lost workdays are from *Recordkeeping Requirements under the Occupational Safety and Health Act of 1970*. For additional data, see *Occupational Injuries and Illnesses in the United States, by Industry*, annual Bureau of Labor Statistics bulletin; BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 17; *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985), pp. 411–14; annual reports in the *Monthly Labor Review*; and annual U.S. Department of Labor press releases.

---

[1] Cost (cents per hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.

[2] Consist of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

[3] Consists of legislative, judicial, administrative, and regulatory activities.

[4] Includes, for example, library, social, and health services.

23. Employment Cost Index, wages and salaries, by occupation and industry group

[1] The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the *Monthly Labor Review* Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.

25. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Quarterly average							
	1984	1985	1984	1985				1986		
			IV	I	II	III	IV	I^p	II^p	III^p
Specified adjustments:										
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:										
First year of contract	3.6	2.6	3.7	3.6	3.5	2.0	2.0	0.4	0.7	1.9
Annual rate over life of contract	2.8	2.7	2.0	2.7	3.4	3.0	1.4	1.2	1.6	1.9
Wage adjustments, settlements covering 1,000 workers or more:										
First year of contract	2.4	2.3	2.3	3.3	2.5	2.0	2.1	.9	1.3	1.6
Annual rate over life of contract	2.4	2.7	1.5	3.2	2.8	3.1	1.9	1.5	2.0	2.0
Effective adjustments:										
Total effective wage adjustment [3]	3.7	3.3	.7	.7	.8	1.2	.5	.6	.7	.6
From settlements reached in period	.8	.7	.3	.1	.2	.2	.1	.0	.2	.1
Deferred from settlements reached in earlier periods	2.0	1.8	.2	.6	.5	.5	.2	.4	.6	.5
From cost-of-living-adjustments clauses	.9	.7	.2	.1	.1	.4	.1	.2	.0	.0

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

p = preliminary.

26. Average specified compensation and wage adjustments, major collective bargaining settlements in private industry situations covering 1,000 workers or more during 4-quarter periods (in percent)

Measure	Average for four quarters ending–							
	1984	1985				1986

[1] Data do not meet publication standards.

p = preliminary.

27. Average effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more during 4-quarter periods (in percent)

Effective wage adjustment	Average for four quarters ending–						
	1985				1986		
	I	II	III	IV	Iᵖ	IIᵖ	IIIᵖ
For all workers:[1]							
Total	3.6	3.5	3.5	3.3	3.1	2.9	2.3
From settlements reached in period	.7	.9	.9	.7	.6	.5	.5
Deferred from settlements reached in earlier period	2.2	1.9	1.8	1.8	1.7	1.6	1.6
From cost-of-living-adjustments clauses	.7	.7	.8	.7	.8	.7	.2
For workers receiving changes:							
Total	4.5	4.2	4.3	4.1	4.0	3.8	3.1
From settlements reached in period	2.9	2.9	2.8	3.4	2.9	2.5	1.7
Deferred from settlements reached in earlier period	4.2	3.9	3.7	3.7	3.5	3.4	3.8
From cost-of-living-adjustments clauses	2.3	2.3	2.8	2.2	2.5	2.0	1.0

[1] Because of rounding total may not equal sum of parts.

ᵖ = preliminary.

28. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, State and local government collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		First 6 months 1986ᵖ
	1984	1985	
Specified adjustments:			
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:			
First year of contract	5.2	4.2	6.7
Annual rate over life of contract	5.4	5.1	6.4
Wage adjustments, settlements covering 1,000 workers or more:			
First year of contract	4.8	4.6	6.1
Annual rate over life of contract	5.1	5.4	6.0
Effective adjustments:			
Total effective wage adjustment [3]	5.0	5.7	1.8
From settlements reached in period	1.9	4.1	.6
Deferred from settlements reached in earlier periods	3.1	1.6	1.2
From cost-of-living-adjustment clauses	(4)	(4)	(4)

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding, total may not equal sum of parts.

[4] Less than 0.05 percent.

ᵖ = preliminary.

29. Work stoppages involving 1,000 workers or more

Measure	Annual totals		1985			1986								
	1984	1985	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.	Mayᵖ	Juneᵖ	Julyᵖ	Aug.ᵖ	Sept.ᵖ
Number of stoppages:														
Beginning in period	62	54	6	3	2	4	3	2	4	6	11	13	10	7
In effect during period	68	61	20	13	9	7	7	6	8	10	15	22	22	17
Workers involved:														
Beginning in period (in thousands)	376.0	323.9	78.6	26.2	8.2	7.6	24.0	11.2	6.1	28.6	198.0	46.7	113.3	37.9
In effect during period (in thousands)	391.0	584.1	119.3	47.0	38.0	12.0	28.4	38.6	17.6	41.2	205.9	66.3	144.8	85.2
Days idle:														
Number (in thousands)	8,499.0	7,079.0	1,428.8	688.2	661.9	170.0	309.5	367.5	297.3	303.6	3,684.3	894.5	1,612.1	1,208.5
Percent of estimated working time[1]	.04	.03	.06	.04	.03	.01	.02	.02	.02	.02	.07	.04	.07	.06

[1] Agricultural and government employees are included in the total employed and total working time: private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in "'Total economy' measure of strike idleness," *Monthly Labor Review*, Octo 1968, pp. 54-56.

ᵖ = preliminary

30. Consumer Price Index for All Urban Consumers: U.S. city average, by expenditure category and commodity or service group; and CPI for Urban Wage Earners and Clerical Workers, all items

(1967=100, unless otherwise indicated)

[1] Area is generally the Standard Metropolitan Statistical Area (SMSA), exclusive of farms. L.A.-Long Beach, Anaheim, Calif. is a combination of two SMSA's, and N.Y., N.Y.-Northeastern N.J. and Chicago, Ill.-Northwestern Ind. are the more extensive Standard Consolidated Areas. Area definitions are those established by the Office of Management and Budget in 1973, except for Denver-Boulder, Colo. which does not include Douglas County. Definitions do not include revisions made since 1973.

[2] Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:

M - Every month.
1 - January, March, May, July, September, and November.
2 - February, April, June, August, October, and December.

[3] Regions are defined as the four Census regions.

The population size classes are aggregations of areas which have urban population as defined:

A-1 - More than 4,000,000.
A-2 - 1,250,000 to 4,000,000.
B - 385,000 to 1,250,000.
C - 75,000 to 385,000.
D - Less than 75,000.

Population size class A is the aggregation of population size classes A-1 and A-2.

- Data not available.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Because each local index is a small subset of the national index, it has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error than the national index. As a result, local area indexes show greater volatility than the national index, although their long-term trends are quite similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in escalator clauses.

32. Annual data: Consumer Price Index all items and major groups

Series	1977	1978	1979	1980	1981	1982	1983	1984	1985

[1] Quarterly rates are for the first month of the quarter.

[2] Major changes in the Italian labor force survey, introduced in 1977, resulted in a large increase in persons enumerated as unemployed. However, many persons reported that they had not actively sought work in the past 30 days, and they have been provisionally excluded for comparability with U.S. concepts. Inclusion of such persons would more than double the Italian unemployment rate shown.

- Data not available.

NOTE: Quarterly figures for France, Germany, and Great Britain are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures.

46. Annual data: Employment status of the civilian working-age population, 10 countries

Lost workdays	36.4	35.4	36.2	38.1	35.8	35.9	35.8	37.0	41.1

[1] Total cases include fatalities.

[2] The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as: (N/EH) X 200,000, where:

N = number of injuries and illnesses or lost workdays.

EH = total hours worked by all employees during calendar year.

200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year.)

[3] Excludes farms with fewer than 11 employees since 1976.

MONTHLY LABOR REVIEW

Index of Volume 109
January 1986 through December 1986

INDEX TO VOLUME 109
JANUARY 1986 THROUGH DECEMBER 1986

ABSENTEEISM

Missed work and lost hours, May 1985. 1986 Nov. 26–30.

ACCIDENTS (See Work injuries.)

ARBITRATION (See also Collective bargaining.)

Postal arbitration: issues surrounding the award, The 1984. 1986 June. 31–32.

AUSTRALIA

An international comparison of labor force participation, 1977–84. 1986 May. 3–12.
How do Australian unions maintain standing during adverse periods? 1986 June. 37–39.
International experiences with technological change. 1986 Mar. 35–40.

AUTOMATION (See Technological change.)

AUTO WORKERS (UAW)

Constitutional convention marks golden anniversary of the UAW. 1986 Oct. 23–25.

BELGIUM

International trends in productivity and unit labor costs in manufacutring. 1986 Dec. 12–17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

CANADA

An international comparison of labor force participation, 1977–84. 1986 May. 3–12.
International experiences with technological change. 1986 Mar. 35–40.
International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12–17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

COLLECTIVE BARGAINING (See also Arbitration.)

Collective bargaining during 1986: pressures to curb costs remain. 1986 Jan. 16–33.
Communications Workers focus on bargaining with AT&T. 1986 July. 37–39.
Labor and management continue to combat mutual problems in 1985. 1986 Jan. 3–15.
Steelworkers press organizing and coordinated bargaining. 1986 Nov. 48–49.
Postal arbitration: issues surrounding the award, The 1984. 1986 June. 31–32.
Wage restraints continue in 1985 major contracts. 1986 Apr. 22–28.

COMPUTERS (See Technological change.)

CONFERENCES AND CONVENTIONS

Communications Workers of America (CWA), 48th annual convention, May 24, 1986. 1986 July. 37–39.
Industrial Relations Research Association, 38th annual meeting, December 1985, Papers from. 1986 Apr. 45–49; 1986 May. 28–34; 1986 June. 28–39.
United Automobile, Aerospace and Agricultural Implement Workers of America (UAW), 28th constitutional convention, June 1–6, 1986. 1986 Oct. 23–25.
United Steelworkers of America (AFL-CIO, CLC), 23rd constitutional convention, August 25–29, 1986. 1986 Nov. 48–49.

CONSTRUCTION

Foreign housing voucher systems: evolution and strategies. 1986 May. 21–27.

CONSUMER EXPENDITURES

Consumer expenditures: results from the Diary and Interview surveys. 1986 June. 14–18.
Distribution of consumption examined using aggregate expenditure shares. 1986 Apr. 50–53.
Spending patterns of older persons revealed in expenditure survey. 1986 Oct. 15–17.

CONSUMER PRICE INDEX (See also Prices.)

A half-year decline in inflation: its antecedents and structure. 1986 Oct. 3–14.
Inflation remained mild again during 1985. 1986 Apr. 17–21.
Revised Consumer Price Index: changes in definitions and availability, The. 1986 July. 15–23.

COST OF LIVING

Spending patterns of older persons revealed in expenditure survey. 1986 Oct. 15–17.

DENMARK

International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12—17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

DEREGULATION

Airline deregulation and labor relations. 1986 June. 29–30.

DISCRIMINATION (See Equal Employment Opportunity.)

DISPLACED WORKERS

Displaced workers: one year later. 1986 July. 40–42.

EARNINGS AND WAGES

General

BLS area wage surveys will cover more areas. 1986 June. 19–23.
BLS white-collar pay survey now covers small firms. 1986 Oct. 26–28.
Declining middle class: a further analysis, The. 1986 Sept. 22–27.
Hourly paid workers: who they are and what they earn. 1986 Feb. 20–26.
Measuring wage premiums for job risks. 1986 June. 42–43.
Overtime work: an expanded view. 1986 Nov. 36–39.
Preferred hours of work and corresponding earnings. 1986 Nov. 40–44.
Reconciling divergent trends in real income. 1986 July. 24–29.
Wage restraints continue in 1985 major contracts. 1986 Apr. 22–28.
Weekly earnings in 1985: a look at more than 200 occupations. 1986 Sept. 28–32.

Specified industries and occupations

Minimum wage stability affects shirt and nightwear industry pay. 1986 Mar. 32–33.
Occupational pay in the manufacture of men's and boys' suits and coats. 1986 Jan. 67–68.
Occupational pay in textile dyeing and finishing plants. 1986 Dec 33–34.
Occupational pay structure in petroleum refineries. 1986 July. 43–44.
Postal arbitration: issues surrounding the award, The 1984. 1986 June. 31–32.

ECONOMIC DEVELOPMENT AND GROWTH

Business cycle effects on productivity and costs, 1947–86. 1986 Dec. 18–22.

ECONOMIC POLICIES AND PROGRAMS

Sensitivity of BLS economic projections to exogenous variables. 1986 Dec. 23–29.

EDUCATION AND TRAINING

What happened to the high school class of 1985? 1986 Oct. 28–30.

ELECTRONICS

Employment lessons from the electronics industry. 1986 Feb. 27–36.

EMPLOYMENT (See also Labor force; Unemployment.)

A view of the 80's. 1986 Sept. 2.
An analysis of regional employment growth, 1973–85. 1986 July. 3–14.
Business services industry sets pace in employment growth, The. 1986 Apr. 29–36.
Declining middle class: a further analysis, The. 1986 Sept. 22–27.
Deindustrialization and the shift to services. 1986 June. 3–13.
Displaced workers: one year later. 1986 July. 40–42.
Employment and unemployment: developments in 1985. 1986 Feb. 3–12.
Employment benchmark. 1986 June. 2.
Employment expansion in retail trade, 1973–85, The. 1986 Aug. 9–16.
Employment growth in the temporary help industry. 1986 Apr. 37–44.
Employment in health services: long-term trends and projections. 1986 Aug. 17–36.
Employment lessons from the electronics industry. 1986 Feb. 27–36.
Employment up, unemployment stable in the first half of 1986. 1986 Aug. 3–8.
Hospital employment under revised medicare payment schedules. 1986 Aug. 37–45.
ILO adopts asbestos standard, focuses on employment issues. 1986 Oct. 31–32.
Part-time workers: who are they? 1986 Feb. 13–19.
Temporary help workers: who they are, what jobs they hold. 1986 Nov. 45–47.
Work experience profile, 1984: the effects of recovery continue. 1986 Feb. 37–43.

EQUAL EMPLOYMENT OPPORTUNITY

Sex segregation. 1986 Feb. 2.

FOREIGN TRADE

Aggregate export price comparisons developed for U.S., Germany, Japan. 1986 June. 40–41.
Import, export prices reflect declining dollar and oversupply in 1985. 1986 Apr. 3–16.

FRANCE

European job creation in the wake of plant closings and layoffs. 1986 Oct. 18–22.
International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12–17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

GERMANY

Aggregate export price comparisons developed for U.S., Germany, Japan. 1986 June. 40–41.
An international comparison of labor force participation, 1977-84. 1986 May. 3–12.
International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12–17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.
West German labor unrest: are unions losing ground to worker councils? 1986 Feb. 46–48.

GREAT BRITAIN (See United Kingdom.)

HEALTH AND INSURANCE PLANS

Health insurance trends in cost control and coverage. 1986 Sept. 3–8.
Hospital employment under revised medicare payment schedules. 1986 Aug. 37–45.

HEALTH AND SAFETY (See also Work injuries and illnesses.)

BLS and Alice Hamilton: pioneers in industrial health. 1986 June. 24–27.
Employment in health services: long-term trends and projections, 1986 Aug. 17–36.
ILO adopts asbestos standard, focuses on employment issues, 1986 Oct. 31–32.

HOSPITALS

Hospital employment under revised medicare payment schedules. 1986 Aug. 37–45.

HOUSING (See Construction.)

HOURS OF WORK

Computer-aided telephone interviewing used in the Hours at Work Survey. 1986 May. 39–41.
Moonlighting by women jumped to record highs. 1986 Nov. 22–25.
Overtime work: an expanded view. 1986 Nov. 36–39.
Part-time workers: who are they? 1986 Feb. 13–19.
Preferred hours of work and corresponding earnings. 1986 Nov. 40–44.
Shift work and flexitime: how prevalent are they? 1986 Nov. 14–21.
Growing diversity of work schedules, The. 1986 Nov. 7–13.
Work at home: new findings from the Current Population Survey. 1986 Nov. 31–35.
Work schedules of Americans: an overview of new findings. 1986 Nov. 3–6.

IMMIGRATION

Estimating the number of undocumented aliens. 1986 Sept. 33.
Immigration effects. 1986 Mar. 2.

IMPORTS (See Foreign trade.)

INCOME (See Earnings and wages.)

INDUSTRIAL RELATIONS RESEARCH ASSOCIATION

Thirty-Eighth Annual Meeting. Papers from, 1985 Dec. 1986 Apr. 45–49; 1986 May. 28–34; 1986 June. 28–39.

INFLATION

A half-year decline in inflation: its antecedents and structure. 1986 Oct. 3–14.
Inflation remained mild again during 1985. 1986 Apr. 17–21.

INTERNATIONAL LABOR ORGANIZATION

ILO adopts asbestos standard, focuses on employment issues. 1986 Oct. 31–32.

ITALY

European job creation in the wake of plant closings and layoffs. 1986 Oct. 18–22.
International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12–17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

JAPAN

Aggregate export price comparisons developed for U.S., Germany, Japan. 1986 June. 40–41.
An international comparison of labor force participation, 1977–84. 1986 May. 3–12.
International experiences with technological change. 1986 Mar. 35–40.
International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12–17.
Labor market segmentation in Japan: how rigid is it? 1986 June. 35–37.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

JOB CREATION

European job creation in the wake of plant closings and layoffs. 1986 Oct. 18–22.

LABOR FORCE

An international comparison of labor force participation, 1977–84. 1986 May. 3–12.
Business services industry sets pace in employment growth, The. 1986 Apr. 29–36.
Changing demographics. 1986 Aug. 2.
Employment and unemployment: developments in 1985. 1986 Feb. 3–12.
Employment growth in the temporary help industry. 1986 Apr. 37–44.
Employment up, unemployment stable in the first half of 1986. 1986 Aug. 3–8.
Hourly paid workers: who they are and what they earn. 1986 Feb. 20–26.
Military and civilian wives: update on the labor force gap. 1986 Dec. 31–33.
Part-time workers: who are they? 1986 Feb. 13–19.
Rise in mothers' labor force activity includes those with infants. 1986 Feb. 43–45.
Temporary help workers: who they are and what jobs they hold. 1986 Nov. 45–47.
What happened to the high school class of 1985? 1986 Oct. 28–30.
Women veterans total 1 million in first half of 1986. 1986 Dec. 30–31.
Work experience profile, 1984: the effects of recovery continue. 1986 Feb. 37–43.
Work, poverty, and the working poor: a multifaceted problem. 1986 Sept. 17–21.
Work schedules of Americans: an overview of new findings. 1986 Nov. 3–6.

LABOR HISTORY

BLS and Alice Hamilton: pioneers in industrial health. 1986 June. 24–27.
Ellis Island a welcome site? Only after years of reform. 1986 July. 30–36.

LABOR LAW

Changes in unemployment insurance legislation during 1985. 1986 Jan. 55–60.
Key workers' compensation laws enacted by States in 1985. 1986 Jan. 61–67.
Labor law study. 1986 July. 2.
State labor legislation enacted in 1985. 1986 Jan. 34–54.

LABOR-MANAGEMENT RELATIONS

Competitiveness. 1986 Mar. 2.
Environmental factors in the labor-management relationship. 1986 Apr. 47–48.
Labor and management continue to combat mutual problems in 1985. 1986 Jan. 3–15.
'Union avoidance:' management's new industrial relations strategy. 1986 Apr. 45–46.
Union response to changes in printing technology. 1986 May. 37–38.

LABOR MARKET

Airline deregulation and labor relations. 1986 June. 29–30.
An analysis of regional employment growth, 1973-85. 1986 July. 3–14.
Declining middle class: a further analysis, The. 1986 Sept. 22–27.
Labor-market data: supplementary sources. 1986 June. 28–29.
Labor market segmentation in Japan: how rigid is it? 1986 June. 35–37.

LABOR ORGANIZATIONS

Canadian unions achieve strong gains in membership. 1986 Apr. 48–49.
Communications Workers focus on bargaining with AT&T. 1986 July. 37–39.
How do Australian unions maintain standing during adverse periods? 1986 June. 37–39.
Union membership trends: a study of the Garment Workers. 1986 June. 33–35.
Union response to changes in printing technology: another view. 1986 May. 37–38.
West German labor unrest: are unions losing ground to worker councils? 1986 Feb. 46–48.

LAYOFFS

A new leading indicator: workers recently laid off. 1986 May. 35–37.
European job creation in the wake of plant closings and layoffs. 1986 Oct. 18–22.

MANUFACTURING

Computer manufacturing enters a new era of growth. 1986 Sept. 9–16.
Deindustrialization and the shift to services. 1986 June. 3–13.
International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12–17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

MULTIPLE JOBHOLDERS

Moonlighting by women jumped to record highs. 1986 Nov. 22–25.

NETHERLANDS, THE

International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12–17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

NORWAY

International experiences with technological change. 1986 Mar. 35–40.
International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12–17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

OCCUPATIONAL SAFETY AND HEALTH

BLS and Alice Hamilton: pioneers in industrial health. 1986 June. 24–27.

OLDER WORKERS

Spending patterns of older persons revealed in expenditure survey. 1986 Oct. 15–17.

PLANT SHUTDOWNS

European job creation in the wake of plant closings and layoffs. 1986 Oct. 18–22.

POVERTY (See also Unemployment.)

Work, poverty, and the working poor: a multifaceted problem. 1986 Sept. 17–21.

PRICES

A half-year decline in inflation: its antecedents and structure. 1986 Oct. 3–14.
Aggregate export price comparisons developed for U.S., Germany, Japan. 1986 June. 40–41.
Distribution of consumption examined using aggregate expenditure shares. 1986 Apr. 50–53.
Import, export prices reflect declining dollar and oversupply in 1985. 1986 Apr. 3–16.
Inflation remained mild again during 1985. 1986 Apr. 17–21.
Revised Consumer Price Index: changes in definitions and availability, The. 1986 July. 15–23.

PRODUCER PRICE INDEX

Inflation remained mild again during 1985. 1986 Apr. 17–21.

PRODUCTIVITY

Beauty and barber shops: the trend of labor productivity. 1986 Mar. 21–26.
Computer manufacturing enters a new era of growth. 1986 Sept. 9–16.
Contribution of R&D to productivity growth, The. 1986 Mar. 16–20.
International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12—17.
Measuring single-factor and multifactor productivity. 1986 Dec. 3—11.
Productivity continued to increase in many industries during 1984. 1986 Mar. 11–15.
Productivity and labor costs trends in manufacturing, 12 countries. 1986 Mar. 3–10.
Productivity in the metal doors, sash, and trim industry. 1986 Mar. 27–31.
Trends of labor productivity in metal stamping industries. 1986 May. 13–20.
U.S. productivity growth since 1982: the post-recession experience. 1986 Dec. 18–22.

PROJECTIONS

Employment in health services: long-term trends and projections. 1986 Aug. 17–36.
Sensitivity of BLS economic projections to exogenous variables. 1986 Dec. 23–29.

SALARIES (See Earnings and wages.)

SERVICE SECTOR

Business services industry sets pace in employment growth, The. 1986 Apr. 29–36.
Deindustrialization and the shift to services. 1986 June. 3–13.

STATE GOVERNMENT

Changes in unemployment insurance legislation during 1985. 1986 Jan. 55–60.
Key workers' compensation laws enacted by States in 1985. 1986 Jan. 61–67.
State labor legislation enacted in 1985. 1986 Jan. 34–54.

STATISTICS

Labor market data: supplementary sources. 1986 June. 28–29.

STEELWORKERS

Steelworkers press organizing and coordinated bargaining. 1986 Nov. 48–49.

SURVEY METHODS

BLS area wage surveys will cover more areas. 1986 June. 19–23.
Computer-aided telephone interviewing used in the Hours at Work Survey. 1986 May. 39–41.
Expert panel offers suggestions on 1990 census methodology. 1986 Mar. 33–34.
Interview group bias. 1986 June. 43.
Revised Consumer Price Index: changes in definitions and availability, The. 1986 July. 15–23.

SWEDEN

An international comparison of labor force participation, 1977–84. 1986 May. 3–12.
International experiences with technological change. 1986 Mar. 35–40.
International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12—17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

TECHNOLOGICAL CHANGE

Computer-aided telephone interviewing used in the Hours at Work Survey. 1986 May. 39–41.
Computer manufacturing enters a new era of growth. 1986 Sept. 9–16.
Contribution of R&D to productivity growth, The. 1986 Mar. 16–20.
Employment lessons from the electronics industry. 1986 Feb. 27–36.
International experiences with technological change. 1986 Mar. 35–40.

UNEMPLOYMENT

A new leading indicator: workers recently laid off. 1986 May. 35–37.
Displaced workers: one year later. 1986 July. 40–42.
Employment and unemployment: developments in 1985. 1986 Feb. 3–12.
Employment up, unemployment stable in the first half of 1986. 1986 Aug. 3–8.

UNEMPLOYMENT INSURANCE

Changes in unemployment insurance legislation during 1985. 1986 Jan. 55–60.

UNION MEMBERSHIP

Canadian unions achieve strong gains in membership. 1986 Apr. 48–49.
Union membership of employed wage and salary workers, 1985. 1986 May. 44–46.
Union membership trends: a study of the Garment Workers. 1986 June. 33–35.

UNIONS (See Labor organizations.)

UNITED KINGDOM

European job creation in the wake of plant closings and layoffs. 1986 Oct. 18–22.
International experiences with technological change. 1986 Mar. 35–40.
International trends in productivity and unit labor costs in manufacturing. 1986 Dec. 12-17.
Productivity and labor cost trends in manufacturing, 12 countries. 1986 Mar. 3–10.

VETERANS

Women veterans total 1 million in first half of 1986. 1986 Dec. 30–31.

WAGES (See Earnings and wages.)

WHITE-COLLAR WORKERS

BLS white-collar pay survey now covers small firms. 1986 Oct. 26–28.

WOMEN

Military and civilian wives: update on the labor force gap. 1986 Dec. 31—33.

Moonlighting by women jumped to record highs. 1986 Nov. 22–25.
Rise in mothers' labor force activity includes those with infants. 1986 Feb. 43–45.
Women veterans total 1 million in first half of 1986. 1986 Dec. 30–31.

WORK AT HOME

Work at home: new findings from the Current Population Survey. 1986 Nov. 31–35.

WORK INJURIES AND ILLNESSES

Occupational illness. 1986 Jan. 2.
Work-related deaths in 1984: BLS survey findings. 1986 May. 42–44.

WORK SHARING

Short-time compensation: assessing the issues. 1986 May. 28–30.
Short-time compensation: the AFL-CIO perspective. 1986 May. 33–34.
Work sharing programs: an evaluation of their use. 1986 May. 31–33.

WORKERS' COMPENSATION

Key workers' compensation laws enacted by States in 1985. 1986 Jan. 61–67.

WORKING LIFE

Work experience profile, 1984: the effects of recovery continue. 1986 Feb. 37–43.

YOUTH (See Labor force.)

DEPARTMENTS

Book Notes. June issue.
Book Reviews. Each issue except April.

Women's role in the family

At the extremes, . . . the economic conditions of the United States and Mexico have different effects on the employment behavior of married women. The higher cost of living in the United States compels women to seek work, even over the initial objections of their husbands. The specific conditions of that employment must, however, mesh with wives' dual role as wage-earner and housekeeper/babysitter. In contrast, the lower cost of living and lack of alternative employment in Mexico bolster husbands' traditional objections to wives' employment.

. . . the type and duration of employment experienced by married farm worker women is strongly influenced by their generally disadvantaged status, by their role in the family, and by the economic position of the family. In almost all instances, women's work careers are organized in such a way as to carry out the traditional duties of wife and mother, in addition to that of wage earner. A wife's wage may represent an integral part of the family budget, particularly in the case of families living in the United States and border areas, but the range of work opportunities and the duration of employment are limited by her subordinate status in the family. Thus, the availability of work in low skill, seasonal production allows women to carry out the dual roles of wife and wage-earner. At the same time, however, the availability of this attractive labor pool facilitates expansion of those jobs.
